            "Resource": [  
                "arn:aws:s3:::awsexamplebucket1"  
            ]  
        },  
        {  
            "Sid": "statement2",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountA-ID:user/Dave"  
            },  
            "Action": [  
                "s3:GetObject"  
            ]  
        }  
    ]  
}
```

```
        ],
        "Resource": [
            "arn:aws:s3:::awsexamplebucket1/*"
        ]
    }
]
```

- b. Create an inline policy for the user Dave by using the following policy. The policy grants Dave the s3:PutObject permission. You need to update the policy by providing your bucket name.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PermissionForObjectOperations",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::awsexamplebucket1/*"
            ]
        }
    ]
}
```

For instructions, see [Managing IAM policies](#) in the *IAM User Guide*. Note you need to sign in to the console using Account A credentials.

Step 2: Test permissions

Using Dave's credentials, verify that the permissions work. You can use either of the following two procedures.

Test permissions using the AWS CLI

1. Update the AWS CLI config file by adding the following UserDaveAccountA profile. For more information, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDaveAccountA]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

- Verify that Dave can perform the operations as granted in the user policy. Upload a sample object using the following AWS CLI put-object command.

The --body parameter in the command identifies the source file to upload. For example, if the file is in the root of the C: drive on a Windows machine, you specify c:\HappyFace.jpg. The --key parameter provides the key name for the object.

```
aws s3api put-object --bucket awsexamplebucket1 --key HappyFace.jpg --
body HappyFace.jpg --profile UserDaveAccountA
```

Run the following AWS CLI command to get the object.

```
aws s3api get-object --bucket awsexamplebucket1 --key HappyFace.jpg OutputFile.jpg
--profile UserDaveAccountA
```

Test permissions using the AWS Tools for Windows PowerShell

- Store Dave's credentials as AccountADave. You then use these credentials to PUT and GET an object.

```
set-awscredentials -AccessKey AccessKeyId -SecretKey SecretAccessKey -storeas
AccountADave
```

- Upload a sample object using the AWS Tools for Windows PowerShell Write-S3Object command using user Dave's stored credentials.

```
Write-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file HappyFace.jpg
-StoredCredentials AccountADave
```

Download the previously uploaded object.

```
Read-S3Object -bucketname awsexamplebucket1 -key HappyFace.jpg -file Output.jpg -  
StoredCredentials AccountADave
```

Example 2: Bucket owner granting cross-account bucket permissions

Important

Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see [Understanding cross-account permissions and using IAM roles](#).

Topics

- [Preparing for the walkthrough](#)
- [Step 1: Do the Account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: \(Optional\) Try explicit deny](#)
- [Step 4: Clean up](#)

An AWS account—for example, Account A—can grant another AWS account, Account B, permission to access its resources such as buckets and objects. Account B can then delegate those permissions to users in its account. In this example scenario, a bucket owner grants cross-account permission to another account to perform specific bucket operations.

Note

Account A can also directly grant a user in Account B permissions using a bucket policy. However, the user will still need permission from the parent account, Account B, to which the user belongs, even if Account B doesn't have permissions from Account A. As long as the user has permission from both the resource owner and the parent account, the user will be able to access the resource.

The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy granting cross-account permissions to Account B to perform specific bucket operations.

Note that administrator user in Account B will automatically inherit the permissions.

2. Account B administrator user attaches user policy to the user delegating the permissions it received from Account A.
3. User in Account B then verifies permissions by accessing an object in the bucket owned by Account A.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in them. In accordance with the IAM guidelines (see [About using an administrator user to create resources and grant permissions](#)), we don't use the root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Preparing for the walkthrough

1. Make sure you have two AWS accounts and that each account has one administrator user as shown in the table in the preceding section.
 - a. Sign up for an AWS account, if needed.
 - b. Using Account A credentials, sign in to the [IAM console](#) to create the administrator user:
 - i. Create user **AccountAadmin** and note the security credentials. For instructions, see [Creating an IAM user in Your AWS account](#) in the *IAM User Guide*.
 - ii. Grant administrator privileges to **AccountAadmin** by attaching a user policy giving full access. For instructions, see [Working with Policies](#) in the *IAM User Guide*.
 - c. While you are in the IAM console, note the **IAM user Sign-In URL** on the **Dashboard**. All users in the account must use this URL when signing in to the AWS Management Console.

For more information, see [How Users Sign in to Your Account](#) in *IAM User Guide*.

- d. Repeat the preceding step using Account B credentials and create administrator user **AccountBadmin**.
2. Set up either the AWS Command Line Interface (AWS CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:
 - If using the AWS CLI, create two profiles, AccountAadmin and AccountBadmin, in the config file.
 - If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

3. Save the administrator user credentials, also referred to as profiles. You can use the profile name instead of specifying credentials for each command you enter. For more information, see [Setting up the tools for the walkthroughs](#).
 - a. Add profiles in the AWS CLI credentials file for each of the administrator users, AccountAadmin and AccountBadmin, in the two accounts.

```
[AccountAadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
```

```
region = us-east-1

[AccountBadmin]
aws_access_key_id = access-key-ID
aws_secret_access_key = secret-access-key
region = us-east-1
```

- b. If you're using the AWS Tools for Windows PowerShell, run the following command.

```
set-awscredentials -AccessKey AcctA-access-key-ID -SecretKey AcctA-secret-access-key -storeas AccountAadmin
set-awscredentials -AccessKey AcctB-access-key-ID -SecretKey AcctB-secret-access-key -storeas AccountBadmin
```

Step 1: Do the Account A tasks

Step 1.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket

1. In the Amazon S3 console, create a bucket. This exercise assumes the bucket is created in the US East (N. Virginia) AWS Region and is named *amzn-s3-demo-bucket*.

For instructions, see [Creating a bucket](#).

2. Upload a sample object to the bucket.

For instructions, go to [Step 2: Upload an object to your bucket](#).

Step 1.3: Attach a bucket policy to grant cross-account permissions to Account B

The bucket policy grants the s3:GetLifecycleConfiguration and s3>ListBucket permissions to Account B. It's assumed that you're still signed in to the console using **AccountAadmin** user credentials.

1. Attach the following bucket policy to *amzn-s3-demo-bucket*. The policy grants Account B permission for the s3:GetLifecycleConfiguration and s3>ListBucket actions.

For instructions, see [Adding a bucket policy by using the Amazon S3 console](#).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Example permissions",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountB-ID:root"  
            },  
            "Action": [  
                "s3:GetLifecycleConfiguration",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket"  
            ]  
        }  
    ]  
}
```

2. Verify that Account B (and thus its administrator user) can perform the operations.

- Verify using the AWS CLI

```
aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin  
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --  
profile AccountBadmin
```

- Verify using the AWS Tools for Windows PowerShell

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBadmin  
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -  
StoredCredentials AccountBadmin
```

Step 2: Do the Account B tasks

Now the Account B administrator creates a user, Dave, and delegates the permissions received from Account A.

Step 2.1: Sign in to the AWS Management Console

Using the IAM user sign-in URL for Account B, first sign in to the AWS Management Console as **AccountBadmin** user.

Step 2.2: Create user Dave in Account B

In the [IAM Console](#), create a user, **Dave**.

For instructions, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

Step 2.3: Delegate permissions to user Dave

Create an inline policy for the user Dave by using the following policy. You will need to update the policy by providing your bucket name.

It's assumed that you're signed in to the console using **AccountBadmin** user credentials.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Example",
            "Effect": "Allow",
            "Action": [
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
        }
    ]
}
```

For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.

Step 2.4: Test permissions

Now Dave in Account B can list the contents of *amzn-s3-demo-bucket* owned by Account A. You can verify the permissions using either of the following procedures.

Test permissions using the AWS CLI

1. Add the UserDave profile to the AWS CLI config file. For more information about the config file, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDave]
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

2. At the command prompt, enter the following AWS CLI command to verify Dave can now get an object list from the *amzn-s3-demo-bucket* owned by Account A. Note the command specifies the UserDave profile.

```
aws s3 ls s3://amzn-s3-demo-bucket --profile UserDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-bucket-lifecycle configuration—Amazon S3 returns permission denied.

```
aws s3api get-bucket-lifecycle-configuration --bucket amzn-s3-demo-bucket --profile UserDave
```

Test permissions using AWS Tools for Windows PowerShell

1. Store Dave's credentials as AccountBDave.

```
set-awscredentials -AccessKey AccessKeyID -SecretKey SecretAccessKey -storeas AccountBDave
```

2. Try the List Bucket command.

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Dave doesn't have any other permissions. So, if he tries any other operation—for example, the following get-s3bucketlifecycleconfiguration—Amazon S3 returns permission denied.

```
get-s3bucketlifecycleconfiguration -BucketName amzn-s3-demo-bucket -  
StoredCredentials AccountBDave
```

Step 3: (Optional) Try explicit deny

You can have permissions granted by using an access control list (ACL), a bucket policy, or a user policy. But if there is an explicit deny set by either a bucket policy or a user policy, the explicit deny takes precedence over any other permissions. For testing, update the bucket policy and explicitly deny Account B the s3>ListBucket permission. The policy also grants s3>ListBucket permission. However, explicit deny takes precedence, and Account B or users in Account B will not be able to list objects in *amzn-s3-demo-bucket*.

1. Using credentials of user AccountAadmin in Account A, replace the bucket policy by the following.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Example permissions",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountB-ID:root"  
            },  
            "Action": [  
                "s3:GetLifecycleConfiguration",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket"  
            ]  
        },  
        {  
            "Sid": "Deny permission",  
            "Effect": "Deny",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountB-ID:root"  
            },  
            "Action": [  
                "s3>ListBucket"  
            ]  
        }  
    ]  
}
```

```
        ],
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
        ]
    }
]
```

- Now if you try to get a bucket list using AccountBadmin credentials, access is denied.

- Using the AWS CLI, run the following command:

```
aws s3 ls s3://amzn-s3-demo-bucket --profile AccountBadmin
```

- Using the AWS Tools for Windows PowerShell, run the following command:

```
get-s3object -BucketName amzn-s3-demo-bucket -StoredCredentials AccountBDave
```

Step 4: Clean up

- After you're done testing, you can do the following to clean up:
 - Sign in to the AWS Management Console ([AWS Management Console](#)) using Account A credentials, and do the following:
 - In the Amazon S3 console, remove the bucket policy attached to **amzn-s3-demo-bucket**. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the AccountAadmin user.
- Sign in to the [IAM Console](#) using Account B credentials. Delete user AccountBadmin. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.

Example 3: Bucket owner granting permissions to objects it does not own

Important

Granting permissions to IAM roles is a better practice than granting permissions to individual users. To learn how to do this, see [Understanding cross-account permissions and using IAM roles](#).

Topics

- [Step 0: Preparing for the walkthrough](#)
- [Step 1: Do the Account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: Test permissions](#)
- [Step 4: Clean up](#)

The scenario for this example is that a bucket owner wants to grant permission to access objects, but the bucket owner doesn't own all objects in the bucket. For this example, the bucket owner is trying to grant permission to users in its own account.

A bucket owner can enable other AWS accounts to upload objects. By default, the bucket owner doesn't own objects written to a bucket by another AWS account. Objects are owned by the accounts that write them to an S3 bucket. If the bucket owner doesn't own objects in the bucket, the object owner must first grant permission to the bucket owner using an object access control list (ACL). Then, the bucket owner can grant permissions to an object that they don't own. For more information, see [Amazon S3 bucket and object ownership](#).

If the bucket owner applies the bucket owner enforced setting for S3 Object Ownership for the bucket, the bucket owner will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts.

Note

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are

disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

In this example, we assume the bucket owner has not applied the bucket owner enforced setting for Object Ownership. The bucket owner delegates permission to users in its own account. The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy with two statements.
 - Allow cross-account permission to Account B to upload objects.
 - Allow a user in its own account to access objects in the bucket.
2. Account B administrator user uploads objects to the bucket owned by Account A.
3. Account B administrator updates the object ACL adding grant that gives the bucket owner full-control permission on the object.
4. User in Account A verifies by accessing objects in the bucket, regardless of who owns them.

For this example, you need two accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In this walkthrough, you don't use

the account root user credentials, according to the recommended IAM guidelines. For more information, see [About using an administrator user to create resources and grant permissions](#). Instead, you create an administrator in each account and use those credentials in creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin

All the tasks of creating users and granting permissions are done in the AWS Management Console. To verify permissions, the walkthrough uses the command line tools, AWS Command Line Interface (AWS CLI) and AWS Tools for Windows PowerShell, so you don't need to write any code.

Step 0: Preparing for the walkthrough

1. Make sure that you have two AWS accounts and each account has one administrator as shown in the table in the preceding section.
 - a. Sign up for an AWS account, if needed.
 - b. Using Account A credentials, sign in to the [IAM Console](#) and do the following to create an administrator user:
 - Create user **AccountAadmin** and note the user's security credentials. For more information about adding users, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.
 - Grant administrator permissions to **AccountAadmin** by attaching a user policy that gives full access. For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.
 - In the [IAM Console Dashboard](#), note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see [How users sign in to your account](#) in *IAM User Guide*.
 - c. Repeat the preceding step using Account B credentials and create administrator user **AccountBadmin**.
2. Set up either the AWS CLI or the Tools for Windows PowerShell. Make sure that you save the administrator credentials as follows:

- If using the AWS CLI, create two profiles, AccountAadmin and AccountBadmin, in the config file.
- If using the Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

Step 1: Do the Account A tasks

Perform the following steps for Account A:

Step 1.1: Sign in to the console

Using the IAM user sign-in URL for Account A, sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and user, and add a bucket policy to grant user permissions

1. In the Amazon S3 console, create a bucket. This exercise assumes that the bucket is created in the US East (N. Virginia) AWS Region, and the name is *amzn-s3-demo-bucket1*.

For instructions, see [Creating a bucket](#).

2. In the [IAM Console](#), create a user **Dave**.

For step-by-step instructions, see [Creating IAM users \(console\)](#) in the *IAM User Guide*.

3. Note the user Dave credentials.
4. In the Amazon S3 console, attach the following bucket policy to *amzn-s3-demo-bucket1* bucket. For instructions, see [Adding a bucket policy by using the Amazon S3 console](#). Follow the steps to add a bucket policy. For information about how to find account IDs, see [Finding your AWS account ID](#).

The policy grants Account B the s3:PutObject and s3>ListBucket permissions. The policy also grants user Dave the s3:GetObject permission.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {
```

```
"Sid": "Statement1",
"Effect": "Allow",
"Principal": {
    "AWS": "arn:aws:iam::AccountB-ID:root"
},
>Action": [
    "s3:PutObject",
    "s3>ListBucket"
],
"Resource": [
    "arn:aws:s3::::amzn-s3-demo-bucket1/*",
    "arn:aws:s3::::amzn-s3-demo-bucket1"
]
},
{
    "Sid": "Statement3",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::AccountA-ID:user/Dave"
    },
    "Action": [
        "s3:GetObject"
    ],
    "Resource": [
        "arn:aws:s3::::amzn-s3-demo-bucket1/*"
    ]
}
]
```

Step 2: Do the Account B tasks

Now that Account B has permissions to perform operations on Account A's bucket, the Account B administrator does the following:

- Uploads an object to Account A's bucket
- Adds a grant in the object ACL to allow Account A, the bucket owner, full control

Using the AWS CLI

1. Using the put-object AWS CLI command, upload an object. The --body parameter in the command identifies the source file to upload. For example, if the file is on the C: drive of a Windows machine, specify c:\HappyFace.jpg. The --key parameter provides the key name for the object.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --body HappyFace.jpg --profile AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object. For information about how to find a canonical user ID, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

```
aws s3api put-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --grant-full-control id="AccountA-CanonicalUserID" --profile AccountBadmin
```

Using the Tools for Windows PowerShell

1. Using the Write-S3Object command, upload an object.

```
Write-S3Object -BucketName amzn-s3-demo-bucket1 -key HappyFace.jpg -file HappyFace.jpg -StoredCredentials AccountBadmin
```

2. Add a grant to the object ACL to allow the bucket owner full control of the object.

```
Set-S3ACL -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -CannedACLName "bucket-owner-full-control" -StoredCreden
```

Step 3: Test permissions

Now verify that user Dave in Account A can access the object owned by Account B.

Using the AWS CLI

1. Add user Dave credentials to the AWS CLI config file and create a new profile, UserDaveAccountA. For more information, see [Setting up the tools for the walkthroughs](#).

```
[profile UserDaveAccountA]
```

```
aws_access_key_id = access-key
aws_secret_access_key = secret-access-key
region = us-east-1
```

- Run the get-object CLI command to download HappyFace.jpg and save it locally. You provide user Dave credentials by adding the --profile parameter.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --key
HappyFace.jpg Outputfile.jpg --profile UserDaveAccountA
```

Using the Tools for Windows PowerShell

- Store user Dave AWS credentials, as UserDaveAccountA, to persistent store.

```
Set-AWSCredentials -AccessKey UserDave-AccessKey -SecretKey UserDave-
SecretAccessKey -storeas UserDaveAccountA
```

- Run the Read-S3Object command to download the HappyFace.jpg object and save it locally. You provide user Dave credentials by adding the -StoredCredentials parameter.

```
Read-S3Object -BucketName amzn-s3-demo-bucket1 -Key HappyFace.jpg -file
HappyFace.jpg -StoredCredentials UserDaveAccountA
```

Step 4: Clean up

- After you're done testing, you can do the following to clean up:

- Sign in to the [AWS Management Console](#) using Account A credentials, and do the following:
 - In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the **AccountAadmin** user. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.
- Sign in to the [AWS Management Console](#) using Account B credentials. In the [IAM Console](#), delete the user **AccountBadmin**.

Example 4 - Bucket owner granting cross-account permission to objects it does not own

Topics

- [Understanding cross-account permissions and using IAM roles](#)
- [Step 0: Preparing for the walkthrough](#)
- [Step 1: Do the account A tasks](#)
- [Step 2: Do the Account B tasks](#)
- [Step 3: Do the Account C tasks](#)
- [Step 4: Clean up](#)
- [Related resources](#)

In this example scenario, you own a bucket and you have enabled other AWS accounts to upload objects. If you have applied the bucket owner enforced setting for S3 Object Ownership for the bucket, you will own all objects in the bucket, including objects written by another AWS account. This approach resolves the issue that objects are not owned by you, the bucket owner. Then, you can delegate permission to users in your own account or to other AWS accounts. Suppose the bucket owner enforced setting for S3 Object Ownership is not enabled. That is, your bucket can have objects that other AWS accounts own.

Now, suppose as a bucket owner, you need to grant cross-account permission on objects, regardless of who the owner is, to a user in another account. For example, that user could be a billing application that needs to access object metadata. There are two core issues:

- The bucket owner has no permissions on those objects created by other AWS accounts. For the bucket owner to grant permissions on objects it doesn't own, the object owner must first grant permission to the bucket owner. The object owner is the AWS account that created the objects. The bucket owner can then delegate those permissions.
- The bucket owner account can delegate permissions to users in its own account (see [Example 3: Bucket owner granting permissions to objects it does not own](#)). However, the bucket owner account can't delegate permissions to other AWS accounts because cross-account delegation isn't supported.

In this scenario, the bucket owner can create an AWS Identity and Access Management (IAM) role with permission to access objects. Then, the bucket owner can grant another AWS account permission to assume the role, temporarily enabling it to access objects in the bucket.

Note

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs.

By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Understanding cross-account permissions and using IAM roles

IAM roles enable several scenarios to delegate access to your resources, and cross-account access is one of the key scenarios. In this example, the bucket owner, Account A, uses an IAM role to temporarily delegate object access cross-account to users in another AWS account, Account C. Each IAM role that you create has the following two policies attached to it:

- A trust policy identifying another AWS account that can assume the role.
- An access policy defining what permissions—for example, `s3:GetObject`—are allowed when someone assumes the role. For a list of permissions you can specify in a policy, see [Policy actions for Amazon S3](#).

The AWS account identified in the trust policy then grants its user permission to assume the role. The user can then do the following to access objects:

- Assume the role and, in response, get temporary security credentials.
- Using the temporary security credentials, access the objects in the bucket.

For more information about IAM roles, see [IAM Roles](#) in the *IAM User Guide*.

The following is a summary of the walkthrough steps:

1. Account A administrator user attaches a bucket policy granting Account B conditional permission to upload objects.
2. Account A administrator creates an IAM role, establishing trust with Account C, so users in that account can access Account A. The access policy attached to the role limits what user in Account C can do when the user accesses Account A.
3. Account B administrator uploads an object to the bucket owned by Account A, granting full-control permission to the bucket owner.
4. Account C administrator creates a user and attaches a user policy that allows the user to assume the role.
5. User in Account C first assumes the role, which returns the user temporary security credentials. Using those temporary credentials, the user then accesses objects in the bucket.

For this example, you need three accounts. The following table shows how we refer to these accounts and the administrator users in these accounts. In accordance with the IAM guidelines (see [About using an administrator user to create resources and grant permissions](#)), we don't use the AWS account root user credentials in this walkthrough. Instead, you create an administrator user in each account and use those credentials when creating resources and granting them permissions.

AWS account ID	Account referred to as	Administrator user in the account
1111-1111-1111	Account A	AccountAadmin
2222-2222-2222	Account B	AccountBadmin
3333-3333-3333	Account C	AccountCadmin

Step 0: Preparing for the walkthrough

Note

You might want to open a text editor, and write down some of the information as you go through the steps. In particular, you will need account IDs, canonical user IDs, IAM user Sign-in URLs for each account to connect to the console, and Amazon Resource Names (ARNs) of the IAM users, and roles.

1. Make sure that you have three AWS accounts and each account has one administrator user as shown in the table in the preceding section.
 - a. Sign up for AWS accounts, as needed. We refer to these accounts as Account A, Account B, and Account C.
 - b. Using Account A credentials, sign in to the [IAM console](#) and do the following to create an administrator user:
 - Create user **AccountAdmin** and note its security credentials. For more information about adding users, see [Creating an IAM user in your AWS account](#) in the *IAM User Guide*.
 - Grant administrator privileges to **AccountAdmin** by attaching a user policy giving full access. For instructions, see [Managing IAM policies](#) in the *IAM User Guide*.
 - In the IAM Console **Dashboard**, note the **IAM User Sign-In URL**. Users in this account must use this URL when signing in to the AWS Management Console. For more information, see [Sign in to the AWS Management Console as an IAM user](#) in the *IAM User Guide*.

- c. Repeat the preceding step to create administrator users in Account B and Account C.
2. For Account C, note the canonical user ID.

When you create an IAM role in Account A, the trust policy grants Account C permission to assume the role by specifying the account ID. You can find account information as follows:

- a. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [Amazon S3 console](#).
- b. Choose the name of an Amazon S3 bucket to view the details about that bucket.
- c. Choose the **Permissions** tab and then choose **Access Control List**.
- d. In the **Access for your AWS account** section, in the **Account** column is a long identifier, such as
c1daexampleaaf850ea79cf0430f33d72579fd1611c97f7ded193374c0b163b6. This is your canonical user ID.

3. When creating a bucket policy, you will need the following information. Note these values:

- **Canonical user ID of Account A** – When the Account A administrator grants conditional upload object permission to the Account B administrator, the condition specifies the canonical user ID of the Account A user that must get full-control of the objects.

 **Note**

The canonical user ID is the Amazon S3–only concept. It is a 64-character obfuscated version of the account ID.

- **User ARN for Account B administrator** – You can find the user ARN in the [IAM Console](#). You must select the user and find the user's ARN in the **Summary** tab.

In the bucket policy, you grant AccountBadmin permission to upload objects and you specify the user using the ARN. Here's an example ARN value:

```
arn:aws:iam::AccountB-ID:user/AccountBadmin
```

4. Set up either the AWS Command Line Interface (CLI) or the AWS Tools for Windows PowerShell. Make sure that you save administrator user credentials as follows:
 - If using the AWS CLI, create profiles, AccountAadmin and AccountBadmin, in the config file.

- If using the AWS Tools for Windows PowerShell, make sure that you store credentials for the session as AccountAadmin and AccountBadmin.

For instructions, see [Setting up the tools for the walkthroughs](#).

Step 1: Do the account A tasks

In this example, Account A is the bucket owner. So user AccountAadmin in Account A will do the following:

- Create a bucket.
- Attach a bucket policy that grants the Account B administrator permission to upload objects.
- Create an IAM role that grants Account C permission to assume the role so it can access objects in the bucket.

Step 1.1: Sign in to the AWS Management Console

Using the IAM user Sign-in URL for Account A, first sign in to the AWS Management Console as **AccountAadmin** user. This user will create a bucket and attach a policy to it.

Step 1.2: Create a bucket and attach a bucket policy

In the Amazon S3 console, do the following:

1. Create a bucket. This exercise assumes the bucket name is **amzn-s3-demo-bucket1**.

For instructions, see [Creating a bucket](#).

2. Attach the following bucket policy. The policy grants conditional permission to the Account B administrator permission to upload objects.

Update the policy by providing your own values for **amzn-s3-demo-bucket1**, **AccountB-ID**, and the **CanonicalUserId-of-AWSaccountA-BucketOwner**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "111",  
            "Effect": "Allow",  
            "Principal": "AWSAccountB-ID",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
        },
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"
    },
    {
        "Sid": "112",
        "Effect": "Deny",
        "Principal": {
            "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
        },
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
        "Condition": {
            "StringNotEquals": {
                "s3:x-amz-grant-full-control": "id=CanonicalUserId-of-
AWSaccountA-BucketOwner"
            }
        }
    }
]
```

Step 1.3: Create an IAM role to allow Account C cross-account access in Account A

In the [IAM Console](#), create an IAM role (**examplerole**) that grants Account C permission to assume the role. Make sure that you are still signed in as the Account A administrator because the role must be created in Account A.

1. Before creating the role, prepare the managed policy that defines the permissions that the role requires. You attach this policy to the role in a later step.
 - a. In the navigation pane on the left, choose **Policies** and then choose **Create Policy**.
 - b. Next to **Create Your Own Policy**, choose **Select**.
 - c. Enter **access-accountA-bucket** in the **Policy Name** field.
 - d. Copy the following access policy and paste it into the **Policy Document** field. The access policy grants the role s3:GetObject permission so, when the Account C user assumes the role, it can only perform the s3:GetObject operation.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*"  
        }  
    ]  
}
```

e. Choose **Create Policy**.

The new policy appears in the list of managed policies.

2. In the navigation pane on the left, choose **Roles** and then choose **Create New Role**.
3. Under **Select Role Type**, select **Role for Cross-Account Access**, and then choose the **Select** button next to **Provide access between AWS accounts you own**.
4. Enter the Account C account ID.

For this walkthrough, you don't need to require users to have multi-factor authentication (MFA) to assume the role, so leave that option unselected.

5. Choose **Next Step** to set the permissions that will be associated with the role.
6. Select the checkbox next to the **access-accountA-bucket** policy that you created, and then choose **Next Step**.

The Review page appears so you can confirm the settings for the role before it's created. One very important item to note on this page is the link that you can send to your users who need to use this role. Users who use the link go straight to the **Switch Role** page with the Account ID and Role Name fields already filled in. You can also see this link later on the **Role Summary** page for any cross-account role.

7. Enter **examplerole** for the role name, and then choose **Next Step**.
8. After reviewing the role, choose **Create Role**.

The **examplerole** role is displayed in the list of roles.

9. Choose the role name **examplerole**.
10. Select the **Trust Relationships** tab.

11. Choose **Show policy document** and verify the trust policy shown matches the following policy.

The following trust policy establishes trust with Account C, by allowing it the `sts:AssumeRole` action. For more information, see [AssumeRole](#) in the *AWS Security Token Service API Reference*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountC-ID:root"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

12. Note the Amazon Resource Name (ARN) of the `examplerole` role that you created.

Later in the following steps, you attach a user policy to allow an IAM user to assume this role, and you identify the role by the ARN value.

Step 2: Do the Account B tasks

The example bucket owned by Account A needs objects owned by other accounts. In this step, the Account B administrator uploads an object using the command line tools.

- Using the `put-object` AWS CLI command, upload an object to `amzn-s3-demo-bucket1`.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --  
body HappyFace.jpg --grant-full-control id="canonicalUserId-ofTheBucketOwner" --  
profile AccountBadmin
```

Note the following:

- The `--Profile` parameter specifies the `AccountBadmin` profile, so the object is owned by Account B.

- The parameter `grant-full-control` grants the bucket owner full-control permission on the object as required by the bucket policy.
- The `--body` parameter identifies the source file to upload. For example, if the file is on the C: drive of a Windows computer, you specify `c:\HappyFace.jpg`.

Step 3: Do the Account C tasks

In the preceding steps, Account A has already created a role, `examplerole`, establishing trust with Account C. This role allows users in Account C to access Account A. In this step, the Account C administrator creates a user (Dave) and delegates him the `sts:AssumeRole` permission it received from Account A. This approach allows Dave to assume the `examplerole` and temporarily gain access to Account A. The access policy that Account A attached to the role limits what Dave can do when he accesses Account A—specifically, get objects in `amzn-s3-demo-bucket1`.

Step 3.1: Create a user in Account C and delegate permission to assume `examplerole`

1. Using the IAM user sign-in URL for Account C, first sign in to the AWS Management Console as **AccountCadmin** user.
2. In the [IAM Console](#), create a user, Dave.

For step-by-step instructions, see [Creating IAM users \(AWS Management Console\)](#) in the *IAM User Guide*.

3. Note the Dave credentials. Dave will need these credentials to assume the `examplerole` role.
4. Create an inline policy for the Dave IAM user to delegate the `sts:AssumeRole` permission to Dave on the `examplerole` role in Account A.
 - a. In the navigation pane on the left, choose **Users**.
 - b. Choose the user name **Dave**.
 - c. On the user details page, select the **Permissions** tab and then expand the **Inline Policies** section.
 - d. Choose **click here (or Create User Policy)**.
 - e. Choose **Custom Policy**, and then choose **Select**.
 - f. Enter a name for the policy in the **Policy Name** field.
 - g. Copy the following policy into the **Policy Document** field.

You must update the policy by providing the *AccountA-ID*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["sts:AssumeRole"],  
            "Resource": "arn:aws:iam::AccountA-ID:role/examplerole"  
        }  
    ]  
}
```

h. Choose **Apply Policy**.

5. Save Dave's credentials to the config file of the AWS CLI by adding another profile, AccountCDave.

```
[profile AccountCDave]  
aws_access_key_id = UserDaveAccessKeyID  
aws_secret_access_key = UserDaveSecretAccessKey  
region = us-west-2
```

Step 3.2: Assume role (examplerole) and access objects

Now Dave can access objects in the bucket owned by Account A as follows:

- Dave first assumes the exempleroles using his own credentials. This will return temporary credentials.
- Using the temporary credentials, Dave will then access objects in Account A's bucket.

1. At the command prompt, run the following AWS CLI assume-role command using the AccountCDave profile.

You must update the ARN value in the command by providing the *AccountA-ID* where exempleroles is defined.

```
aws sts assume-role --role-arn arn:aws:iam::AccountA-ID:role/examplerole --profile AccountCDave --role-session-name test
```

In response, AWS Security Token Service (AWS STS) returns temporary security credentials (access key ID, secret access key, and a session token).

2. Save the temporary security credentials in the AWS CLI config file under the TempCred profile.

```
[profile TempCred]
aws_access_key_id = temp-access-key-ID
aws_secret_access_key = temp-secret-access-key
aws_session_token = session-token
region = us-west-2
```

3. At the command prompt, run the following AWS CLI command to access objects using the temporary credentials. For example, the command specifies the head-object API to retrieve object metadata for the HappyFace.jpg object.

```
aws s3api get-object --bucket amzn-s3-demo-bucket1 --
key HappyFace.jpg SaveFileAs.jpg --profile TempCred
```

Because the access policy attached to exempleroles allows the actions, Amazon S3 processes the request. You can try any other action on any other object in the bucket.

If you try any other action—for example, get-object-acl—you will get permission denied because the role isn't allowed that action.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket1 --key HappyFace.jpg --
profile TempCred
```

We used user Dave to assume the role and access the object using temporary credentials. It could also be an application in Account C that accesses objects in *amzn-s3-demo-bucket1*. The application can obtain temporary security credentials, and Account C can delegate the application permission to assume exempleroles.

Step 4: Clean up

1. After you're done testing, you can do the following to clean up:
 - Sign in to the [AWS Management Console](#) using Account A credentials, and do the following:

- In the Amazon S3 console, remove the bucket policy attached to *amzn-s3-demo-bucket1*. In the bucket **Properties**, delete the policy in the **Permissions** section.
 - If the bucket is created for this exercise, in the Amazon S3 console, delete the objects and then delete the bucket.
 - In the [IAM Console](#), remove the exemplerole you created in Account A. For step-by-step instructions, see [Deleting an IAM user](#) in the *IAM User Guide*.
 - In the [IAM Console](#), remove the **AccountAadmin** user.
2. Sign in to the [IAM Console](#) by using Account B credentials. Delete the user **AccountBadmin**.
 3. Sign in to the [IAM Console](#) by using Account C credentials. Delete **AccountCadmin** and the user Dave.

Related resources

For more information that's related to this walkthrough, see the following resources in the *IAM User Guide*:

- [Tutorial: Delegate Access Across AWS accounts Using IAM Roles](#)
- [Managing IAM policies](#)

Using service-linked roles for Amazon S3 Storage Lens

To use Amazon S3 Storage Lens to collect and aggregate metrics across all your accounts in AWS Organizations, you must first ensure that S3 Storage Lens has trusted access enabled by the management account in your organization. S3 Storage Lens creates a service-linked role (SLR) to allow it to get the list of AWS accounts belonging to your organization. This list of accounts is used by S3 Storage Lens to collect metrics for S3 resources in all the member accounts when the S3 Storage Lens dashboard or configurations are created or updated.

Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up S3 Storage Lens easier because you don't have to add the necessary permissions manually. S3 Storage Lens defines the permissions of its service-linked roles,

and unless defined otherwise, only S3 Storage Lens can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete this service-linked role only after first deleting the related resources. This protects your S3 Storage Lens resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon S3 Storage Lens

S3 Storage Lens uses the service-linked role named **AWSServiceRoleForS3StorageLens** – This enables access to AWS services and resources used or managed by S3 Storage Lens. This allows S3 Storage Lens to access AWS Organizations resources on your behalf.

The S3 Storage Lens service-linked role trusts the following service on your organization's storage:

- `storage-lens.s3.amazonaws.com`

The role permissions policy allows S3 Storage Lens to complete the following actions:

- `organizations:DescribeOrganization`
- `organizations>ListAccounts`
- `organizations>ListAWSAccessForOrganization`
- `organizations>ListDelegatedAdministrators`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Creating a service-linked role for S3 Storage Lens

You don't need to manually create a service-linked role. When you complete one of the following tasks while signed into the AWS Organizations management or the delegate administrator accounts, S3 Storage Lens creates the service-linked role for you:

- Create an S3 Storage Lens dashboard configuration for your organization in the Amazon S3 console.
- PUT an S3 Storage Lens configuration for your organization using the REST API, AWS CLI and SDKs.

 **Note**

S3 Storage Lens will support a maximum of five delegated administrators per organization.

If you delete this service-linked role, the preceding actions will re-create it as needed.

Example policy for S3 Storage Lens service-linked role

Example Permissions policy for the S3 Storage Lens service-linked role

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AwsOrgsAccess",  
            "Effect": "Allow",  
            "Action": [  
                "organizations:DescribeOrganization",  
                "organizations>ListAccounts",  
                "organizations>ListAWSServiceAccessForOrganization",  
                "organizations>ListDelegatedAdministrators"  
            ],  
            "Resource": [  
                "*"  
            ]  
        }  
    ]  
}
```

Editing a service-linked role for Amazon S3 Storage Lens

S3 Storage Lens doesn't allow you to edit the AWSServiceRoleForS3StorageLens service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for Amazon S3 Storage Lens

If you no longer need to use the service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If the Amazon S3 Storage Lens service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForS3StorageLens you must delete all the organization level S3 Storage Lens configurations present in all AWS Regions using the AWS Organizations management or the delegate administrator accounts.

The resources are organization-level S3 Storage Lens configurations. Use S3 Storage Lens to clean up the resources and then use the [IAM Console](#), CLI, REST API, or AWS SDK to delete the role.

In the REST API, AWS CLI, and SDKs, S3 Storage Lens configurations can be discovered using `ListStorageLensConfigurations` in all the Regions where your organization has created S3 Storage Lens configurations. Use the action `DeleteStorageLensConfiguration` to delete these configurations so that you can then delete the role.

Note

To delete the service-linked role, you must delete all the organization-level S3 Storage Lens configurations in all the Regions where they exist.

To delete Amazon S3 Storage Lens resources used by the AWSServiceRoleForS3StorageLens SLR

1. To get a list of your organization level configurations, you must use the `ListStorageLensConfigurations` in every Region that you have S3 Storage Lens configurations. This list can also be obtained from the Amazon S3 console.
2. Delete these configurations from the appropriate Regional endpoints by invoking the `DeleteStorageLensConfiguration` API call or by using the Amazon S3 console.

To manually delete the service-linked role using IAM

After you have deleted the configurations, delete the `AWSServiceRoleForS3StorageLens` SLR from the [IAM Console](#) or by invoking the IAM API `DeleteServiceLinkedRole`, or using the AWS CLI or AWS SDK. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Supported Regions for S3 Storage Lens service-linked roles

S3 Storage Lens supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see [Amazon S3 Regions and Endpoints](#).

Troubleshooting Amazon S3 identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon S3 and IAM.

Topics

- [I received an access denied error](#)
- [I am not authorized to perform an action in Amazon S3](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon S3 resources](#)
- [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#)

I received an access denied error

Verify that there is not an explicit Deny statement against the requester you are trying to grant permissions to in either the bucket policy or the identity-based policy.

For detailed information about troubleshooting access denied errors, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3](#).

I am not authorized to perform an action in Amazon S3

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional *my-example-widget* resource but doesn't have the fictional s3:*GetWidget* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:  
s3:GetWidget on resource: my-example-widget
```

In this case, the policy for the mateojackson user must be updated to allow access to the *my-example-widget* resource by using the s3:*GetWidget* action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to Amazon S3.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon S3. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:  
iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the iam:PassRole action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Amazon S3 resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon S3 supports these features, see [How Amazon S3 works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Troubleshoot access denied (403 Forbidden) errors in Amazon S3

Access denied (HTTP 403 Forbidden) errors appear when AWS explicitly or implicitly denies an authorization request.

- An *explicit denial* occurs when a policy contains a Deny statement for the specific AWS action.
- An *implicit denial* occurs when there is no applicable Deny statement and also no applicable Allow statement.

Because an AWS Identity and Access Management (IAM) policy implicitly denies an IAM principal by default, the policy must explicitly allow the principal to perform an action. Otherwise, the policy implicitly denies access. For more information, see [The difference between explicit and implicit denies](#) in the *IAM User Guide*. For information about the policy evaluation logic that determines whether an access request is allowed or denied, see [Policy evaluation logic](#) in the *IAM User Guide*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

The following topics cover the most common causes of access denied errors in Amazon S3.

 **Note**

For access denied (HTTP 403 Forbidden) errors, Amazon S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

Topics

- [Access denied message examples and how to troubleshoot them](#)
- [Bucket policies and IAM policies](#)
- [Amazon S3 ACL settings](#)
- [S3 Block Public Access settings](#)
- [Amazon S3 encryption settings](#)
- [S3 Object Lock settings](#)
- [VPC endpoint policies](#)
- [AWS Organizations policies](#)
- [Access point settings](#)

 **Note**

If you're trying to troubleshoot a permissions issue, start with the [the section called "Access denied message examples and how to troubleshoot them"](#) section, then go to the [??? section](#). Also be sure to follow the guidance in [the section called "Tips for checking permissions"](#).

Access denied message examples and how to troubleshoot them

Amazon S3 now includes additional context in access denied (HTTP 403 Forbidden) errors for requests made to resources within the same AWS account. This new context includes the type of policy that denied access, the reason for denial, and information about the IAM user or role that requested access to the resource.

This additional context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions.

Most access denied error messages appear in the format User *user-arn* is not authorized to perform *action* on "*resource-arn*" because *context*. In this example, *user-arn* is the [Amazon Resource Name \(ARN\)](#) of the user that doesn't receive access, *action* is the service action that the policy denies, and *resource-arn* is the ARN of the resource on which the policy acts. The *context* field represents additional context about the policy type that explains why the policy denied access.

When a policy explicitly denies access because the policy contains a Deny statement, then the access denied error message includes the phrase with an explicit deny in a *type* policy. When the policy implicitly denies access, then the access denied error message includes the phrase because no *type* policy allows the *action* action.

Important

- Enhanced access denied messages are returned only for same-account requests. Cross-account requests return a generic Access Denied message.

For information about the policy evaluation logic that determines whether a cross-account access request is allowed or denied, see [Cross-account policy evaluation logic](#) in the *IAM User Guide*. For a walkthrough that shows how to grant cross-account access, see [the section called "Granting cross-account permissions"](#).

- Enhanced access denied error messages aren't returned for requests made to directory buckets. Directory bucket requests return a generic Access Denied message.
- If multiple policies of the same policy type deny an authorization request, the access denied error message doesn't specify the number of policies.
- If multiple policy types deny an authorization request, the error message includes only one of those policy types.
- If an access request is denied due to multiple reasons, the error message includes only one of the reasons for denial.

The following examples show the format for different types of access denied error messages and how to troubleshoot each type of message.

Access denied due to a resource control policy – explicit denial

1. Check for a Deny statement for the action in your resource control policies (RCPs). For the following example, the action is s3:GetObject.
2. Update your RCP by removing the Deny statement. For more information, see [Update a resource control policy \(RCP\)](#) in the *AWS Organizations User Guide*.

An error occurred (AccessDenied) when calling the GetObject operation:

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"
with an explicit deny in a resource control policy

Access denied due to a Service Control Policy – implicit denial

1. Check for a missing Allow statement for the action in your service control policies (SCPs). For the following example, the action is s3:GetObject.
2. Update your SCP by adding the Allow statement. For more information, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no service control policy allows the s3:GetObject action

Access denied due to a Service Control Policy – explicit denial

1. Check for a Deny statement for the action in your Service Control Policies (SCPs). For the following example, the action is s3:GetObject.
2. Update your SCP by changing the Deny statement to allow the user the necessary access. For an example of how you can do this, see [Prevent IAM users and roles from making specified changes, with an exception for a specified admin role](#) in the *AWS Organizations User Guide*. For more information about updating your SCP, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject with an explicit deny in a service control policy

Access denied due to a VPC endpoint policy – implicit denial

1. Check for a missing Allow statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is s3:GetObject.
2. Update your VPC endpoint policy by adding the Allow statement. For more information, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject because no VPC endpoint policy allows the s3:GetObject action

Access denied due to a VPC endpoint policy – explicit denial

1. Check for an explicit Deny statement for the action in your virtual private cloud (VPC) endpoint policies. For the following example, the action is s3:GetObject.
2. Update your VPC endpoint policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your VPC endpoint policy, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with an explicit deny in a VPC endpoint policy

Access denied due to a permissions boundary – implicit denial

1. Check for a missing Allow statement for the action in your permissions boundary. For the following example, the action is s3:GetObject.
2. Update your permissions boundary by adding the Allow statement to your IAM policy. For more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"

because no permissions boundary allows the s3:GetObject action

Access denied due to a permissions boundary – explicit denial

1. Check for an explicit Deny statement for the action in your permissions boundary. For the following example, the action is s3:GetObject.
2. Update your permissions boundary by changing the Deny statement in your IAM policy to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [aws:PrincipalAccount](#) in the *IAM User Guide*. For more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::777788889999:user/*MaryMajor* is not authorized to perform:
s3:GetObject with an explicit deny in a permissions boundary

Access denied due to session policies – implicit denial

1. Check for a missing Allow statement for the action in your session policies. For the following example, the action is s3:GetObject.
2. Update your session policy by adding the Allow statement. For more information, see [Session policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform:
s3:GetObject because no session policy allows the s3:GetObject action

Access denied due to session policies – explicit denial

1. Check for an explicit Deny statement for the action in your session policies. For the following example, the action is s3:GetObject.
2. Update your session policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition key with the StringNotEquals condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your session policy, see [Session policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with an explicit deny in a session policy

Access denied due to resource-based policies – implicit denial

Note

Resource-based policies means policies such as bucket policies and access point policies.

1. Check for a missing Allow statement for the action in your resource-based policy. Also check whether the IgnorePublicAcls S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is s3:GetObject.
2. Update your policy by adding the Allow statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

You might also need to adjust your IgnorePublicAcls block public access setting for the bucket, access point, or account. For more information, see [the section called “Access denied due to Block Public Access settings”](#) and [the section called “Configuring bucket and access point settings”](#).

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject because no resource-based policy allows the s3:GetObject action

Access denied due to resource-based policies – explicit denial

Note

Resource-based policies means policies such as bucket policies and access point policies.

1. Check for an explicit Deny statement for the action in your resource-based policy. Also check whether the RestrictPublicBuckets S3 Block Public Access setting is applied on the bucket, access point, or account level. For the following example, the action is s3:GetObject.
2. Update your policy by changing the Deny statement to allow the user the necessary access. For example, you can update your Deny statement to use the aws:PrincipalAccount condition

key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in [the section called “Example 7: Excluding principals from Deny statements”](#). For more information about updating your resource-based policy, see [Resource-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

You might also need to adjust your `RestrictPublicBuckets` block public access setting for the bucket, access point, or account. For more information, see [the section called “Access denied due to Block Public Access settings”](#) and [the section called “Configuring bucket and access point settings”](#).

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with  
an explicit deny in a resource-based policy
```

Access denied due to identity-based policies – implicit denial

1. Check for a missing `Allow` statement for the action in identity-based policies attached to the identity. For the following example, the action is `s3:GetObject` attached to the user `MaryMajor`.
2. Update your policy by adding the `Allow` statement. For more information, see [Identity-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject because no identity-based policy allows the s3:GetObject action
```

Access denied due to identity-based policies – explicit denial

1. Check for an explicit `Deny` statement for the action in identity-based policies attached to the identity. For the following example, the action is `s3:GetObject` attached to the user `MaryMajor`.
2. Update your policy by changing the `Deny` statement to allow the user the necessary access. For example, you can update your `Deny` statement to use the `aws:PrincipalAccount` condition key with the `StringNotEquals` condition operator to allow the specific principal access, as shown in [aws:PrincipalAccount](#) in the *IAM User Guide*. For more information, see [Identity-based policies](#) and [Editing IAM policies](#) in the *IAM User Guide*.

User: arn:aws:iam::123456789012:user/*MaryMajor* is not authorized to perform: s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with an explicit deny in an identity-based policy

Access denied due to Block Public Access settings

The Amazon S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. For more information about how Amazon S3 defines "public," see [The meaning of "public"](#).

By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, IAM user policies, object permissions, or access control lists (ACLs) to allow public access. S3 Block Public Access settings override these policies, permissions, and ACLs. Since April 2023, all Block Public Access settings are enabled by default for new buckets.

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an access point, bucket, or account setting.

The four settings provided by Amazon S3 Block Public Access are as follows:

- **BlockPublicAcls** – This setting applies to PutBucketAcl, PutObjectAcl, PutObject, CreateBucket, CopyObject, and POST Object requests. The BlockPublicAcls setting causes the following behavior:
 - PutBucketAcl and PutObjectAcl calls fail if the specified access control list (ACL) is public.
 - PutObject calls fail if the request includes a public ACL.

- If this setting is applied to an account, then `CreateBucket` calls fail with an HTTP 400 (Bad Request) response if the request includes a public ACL.

For example, when access is denied for a `CopyObject` request because of the `BlockPublicAcls` setting, you receive the following message:

```
An error occurred (AccessDenied) when calling the CopyObject operation:  
User: arn:aws:sts::123456789012:user/MaryMajor is not authorized to  
perform: s3:CopyObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"  
because public access control lists (ACLs) are blocked by the BlockPublicAcls block  
public access setting.
```

- `IgnorePublicAcls` – The `IgnorePublicAcls` setting causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. If your request's permission is granted only by a public ACL, then the `IgnorePublicAcls` setting rejects the request.

Any denial resulting from the `IgnorePublicAcls` setting is implicit. For example, if `IgnorePublicAcls` denies a `GetObject` request because of a public ACL, you receive the following message:

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject because no resource-based policy allows the s3:GetObject action
```

- `BlockPublicPolicy` – This setting applies to `PutBucketPolicy` and `PutAccessPointPolicy` requests.

Setting `BlockPublicPolicy` for a bucket causes Amazon S3 to reject calls to `PutBucketPolicy` if the specified bucket policy allows public access. This setting also causes Amazon S3 to reject calls to `PutAccessPointPolicy` for all of the bucket's same-account access points if the specified policy allows public access.

Setting `BlockPublicPolicy` for an access point causes Amazon S3 to reject calls to `PutAccessPointPolicy` and `PutBucketPolicy` that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.

For example, when access is denied on a `PutBucketPolicy` request because of the `BlockPublicPolicy` setting, you receive the following message:

```
An error occurred (AccessDenied) when calling the PutBucketPolicy operation:  
User: arn:aws:sts::123456789012:user/MaryMajor is not authorized to
```

```
perform: s3:PutBucketPolicy on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name"  
because public policies are blocked by the BlockPublicPolicy block public access setting.
```

- **RestrictPublicBuckets** – The **RestrictPublicBuckets** setting restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and the access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket. This setting also rejects all anonymous (or unsigned) calls.

Any denial resulting from the **RestrictPublicBuckets** setting is explicit. For example, if **RestrictPublicBuckets** denies a **GetObject** request because of a public bucket or access point policy, you receive the following message:

```
User: arn:aws:iam::123456789012:user/MaryMajor is not authorized to perform:  
s3:GetObject on resource: "arn:aws:s3:::amzn-s3-demo-bucket1/object-name" with  
an explicit deny in a resource-based policy
```

For more information about these settings, see [the section called “Block public access settings”](#). To review and update these settings, see [the section called “Configuring block public access”](#).

Bucket policies and IAM policies

Bucket-level operations

If there is no bucket policy in place, then the bucket implicitly allows requests from any AWS Identity and Access Management (IAM) identity in the bucket-owner's account. The bucket also implicitly denies requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're the AWS account root user) is implicitly denied from making any requests. For more information about this evaluation logic, see [Determining whether a request is denied or allowed within an account](#) in the *IAM User Guide*.

Object-level operations

If the object is owned by the bucket-owning account, the bucket policy and IAM user policy will function in the same way for object-level operations as they do for bucket-level operations. For example, if there is no bucket policy in place, then the bucket implicitly allows object requests from

any IAM identity in the bucket-owner's account. The bucket also implicitly denies object requests from any other IAM identities from any other accounts, and anonymous (unsigned) requests. However, if there is no IAM user policy in place, the requester (unless they're the AWS account root user) is implicitly denied from making any object requests.

If the object is owned by an external account, then access to the object can be granted only through object access control lists (ACLs). The bucket policy and IAM user policy can still be used to deny object requests.

Therefore, to ensure that your bucket policy or IAM user policy isn't causing an Access Denied (403 Forbidden) error, make sure that the following requirements are met:

- For same-account access, there must not be an explicit Deny statement against the requester you are trying to grant permissions to, in either the bucket policy or the IAM user policy. If you want to grant permissions by using only the bucket policy and the IAM user policy, there must be at least one explicit Allow statement in one of these policies.
- For cross-account access, there must not be an explicit Deny statement against the requester that you're trying to grant permissions to, in either the bucket policy or the IAM user policy. To grant cross-account permissions by using only the bucket policy and IAM user policy, make sure that both the bucket policy and the IAM user policy of the requester include an explicit Allow statement.

 **Note**

Allow statements in a bucket policy apply only to objects that are [owned by the same bucket-owning account](#). However, Deny statements in a bucket policy apply to all objects regardless of object ownership.

To review or edit your bucket policy

 **Note**

To view or edit a bucket policy, you must have the `s3:GetBucketPolicy` permission.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to view or edit a bucket policy for.
4. Choose the **Permissions** tab.
5. Under **Bucket policy**, choose **Edit**. The **Edit bucket policy** page appears.

To review or edit your bucket policy by using the AWS Command Line Interface (AWS CLI), use the [get-bucket-policy](#) command.

 **Note**

If you get locked out of a bucket because of an incorrect bucket policy, [sign in to the AWS Management Console by using your AWS account root user credentials](#). To regain access to your bucket, make sure to delete the incorrect bucket policy by using your AWS account root user credentials.

Tips for checking permissions

To check whether the requester has proper permissions to perform an Amazon S3 operation, try the following:

- Identify the requester. If it's an unsigned request, then it's an anonymous request without an IAM user policy. If it's a request that uses a presigned URL, then the user policy is the same as the one for the IAM user or role that signed the request.
- Verify that you're using the correct IAM user or role. You can verify your IAM user or role by checking the upper-right corner of the AWS Management Console or by using the [aws sts get-caller-identity](#) command.
- Check the IAM policies that are related to the IAM user or role. You can use one of the following methods:
 - [Test IAM policies with the IAM policy simulator](#).
 - Review the different [IAM policy types](#).
- If needed, [edit your IAM user policy](#).
- Review the following examples of policies that explicitly deny or allow access:
 - Explicit allow IAM user policy: [IAM: Allows and denies access to multiple services programmatically and in the console](#)

- Explicit allow bucket policy: [Granting permissions to multiple accounts to upload objects or set object ACLs for public access](#)
- Explicit deny IAM user policy: [AWS: Denies access to AWS based on the requested AWS Region](#)
- Explicit deny bucket policy: [Require SSE-KMS for all objects written to a bucket](#)

Amazon S3 ACL settings

When checking your ACL settings, first [review your Object Ownership setting](#) to check whether ACLs are enabled on the bucket. Be aware that ACL permissions can be used only to grant permissions and can't be used to reject requests. ACLs also can't be used to grant access to requesters that are rejected by explicit denials in bucket policies or IAM user policies.

The Object Ownership setting is set to bucket owner enforced

If the bucket owner enforced setting is enabled, then ACL settings are unlikely to cause an Access Denied (403 Forbidden) error because this setting disables all ACLs that apply to bucket and objects. Bucket owner enforced is the default (and recommended) setting for Amazon S3 buckets.

The Object Ownership setting is set to bucket owner preferred or object writer

ACL permissions are still valid with the bucket owner preferred setting or the object writer setting. There are two kinds of ACLs: bucket ACLs and object ACLs. For the differences between these two types of ACLs, see [Mapping of ACL permissions and access policy permissions](#).

Depending on the action of the rejected request, [check the ACL permissions for your bucket or the object](#):

- If Amazon S3 rejected a LIST, PUT object, GetBucketAcl, or PutBucketAcl request, then [review the ACL permissions for your bucket](#).

 **Note**

You can't grant GET object permissions with bucket ACL settings.

- If Amazon S3 rejected a GET request on an S3 object, or a [PutObjectAcl](#) request, then [review the ACL permissions for the object](#).

⚠️ Important

If the account that owns the object is different from the account that owns the bucket, then access to the object isn't controlled by the bucket policy.

Troubleshooting an Access Denied (403 Forbidden) error from a GET object request during cross-account object ownership

Review the bucket's [Object Ownership settings](#) to determine the object owner. If you have access to the [object ACLs](#), then you can also check the object owner's account. (To view the object owner's account, review the object ACL setting in the Amazon S3 console.) Alternatively, you can also make a `GetObjectAcl` request to find the object owner's [canonical ID](#) to verify the object owner account. By default, ACLs grant explicit allow permissions for GET requests to the object owner's account.

After you've confirmed that the object owner is different from the bucket owner, then depending on your use case and access level, choose one of the following methods to help address the Access Denied (403 Forbidden) error:

- **Disable ACLs (recommended)** – This method will apply to all objects and can be performed by the bucket owner. This method automatically gives the bucket owner ownership and full control over every object in the bucket. Before you implement this method, check the [prerequisites for disabling ACLs](#). For information about how to set your bucket to bucket owner enforced (recommended) mode, see [Setting Object Ownership on an existing bucket](#).

⚠️ Important

To prevent an Access Denied (403 Forbidden) error, be sure to migrate the ACL permissions to a bucket policy before you disable ACLs. For more information, see [Bucket policy examples for migrating from ACL permissions](#).

- **Change the object owner to the bucket owner** – This method can be applied to individual objects, but only the object owner (or a user with the appropriate permissions) can change an object's ownership. Additional PUT costs might apply. (For more information, see [Amazon S3 pricing](#).) This method grants the bucket owner full ownership of the object, allowing the bucket owner to control access to the object through a bucket policy.

To change the object's ownership, do one of the following:

- You (the bucket owner) can [copy the object](#) back to the bucket.
- You can change the Object Ownership setting of the bucket to bucket owner preferred. If versioning is disabled, the objects in the bucket are overwritten. If versioning is enabled, duplicate versions of the same object will appear in the bucket, which the bucket owner can [set a lifecycle rule to expire](#). For instructions on how to change your Object Ownership setting, see [Setting Object Ownership on an existing bucket](#).

 **Note**

When you update your Object Ownership setting to bucket owner preferred, the setting is only applied to new objects that are uploaded to the bucket.

- You can have the object owner upload the object again with the bucket-owner-full-control canned object ACL.

 **Note**

For cross-account uploads, you can also require the bucket-owner-full-control canned object ACL in your bucket policy. For an example bucket policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- **Keep the object writer as the object owner** – This method doesn't change the object owner, but it does allow you to grant access to objects individually. To grant access to an object, you must have the PutObjectAcl permission for the object. Then, to fix the Access Denied (403 Forbidden) error, add the requester as a [grantee](#) to access the object in the object's ACLs. For more information, see [Configuring ACLs](#).

S3 Block Public Access settings

If the failed request involves public access or public policies, then check the S3 Block Public Access settings on your account, bucket, or access point. For more information about troubleshooting access denied errors related to S3 Block Public Access settings, see [the section called "Access denied due to Block Public Access settings"](#).

Amazon S3 encryption settings

Amazon S3 supports server-side encryption on your bucket. Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it.

By default, Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Amazon S3 also allows you to specify the server-side encryption method when uploading objects.

To review your bucket's server-side encryption status and encryption settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the bucket that you want to check the encryption settings for.
4. Choose the **Properties** tab.
5. Scroll down to the **Default encryption** section and view the **Encryption type** settings.

To check your encryption settings by using the AWS CLI, use the [get-bucket-encryption](#) command.

To check the encryption status of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that contains the object.
4. From the **Objects** list, choose the name of the object that you want to add or change encryption for.

The object's details page appears.

5. Scroll down to the **Server-side encryption settings** section to view the object's server-side encryption settings.

To check your object encryption status by using the AWS CLI, use the [head-object](#) command.

Encryption and permissions requirements

Amazon S3 supports three types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

Based on your encryption settings, make sure that the following permissions requirements are met:

- **SSE-S3** – No extra permissions are required.
- **SSE-KMS (with a customer managed key)** – To upload objects, the `kms:GenerateDataKey` permission on the AWS KMS key is required. To download objects and perform multipart uploads of objects, the `kms:Decrypt` permission on the KMS key is required.
- **SSE-KMS (with an AWS managed key)** – The requester must be from the same account that owns the `aws/s3` KMS key. The requester must also have the correct Amazon S3 permissions to access the object.
- **SSE-C (with a customer provided key)** – No additional permissions are required. You can configure the bucket policy to [require and restrict server-side encryption with customer-provided encryption keys](#) for objects in your bucket.

If the object is encrypted with a customer managed key, make sure that the KMS key policy allows you to perform the `kms:GenerateDataKey` or `kms:Decrypt` actions. For instructions on checking your KMS key policy, see [Viewing a key policy](#) in the *AWS Key Management Service Developer Guide*.

S3 Object Lock settings

If your bucket has [S3 Object Lock](#) enabled and the object is protected by a [retention period](#) or [legal hold](#), Amazon S3 returns an Access Denied (403 Forbidden) error when you try to delete the object.

To check whether the bucket has Object Lock enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. From the **Buckets** list, choose the name of the bucket that you want to review.

4. Choose the **Properties** tab.
5. Scroll down to the **Object Lock** section. Verify whether the **Object Lock** setting is **Enabled** or **Disabled**.

To determine whether the object is protected by a retention period or legal hold, [view the lock information](#) for your object.

If the object is protected by a retention period or legal hold, check the following:

- If the object version is protected by the compliance retention mode, there is no way to permanently delete it. A permanent DELETE request from any requester, including the AWS account root user, will result in an Access Denied (403 Forbidden) error. Also, be aware that when you submit a DELETE request for an object that's protected by the compliance retention mode, Amazon S3 creates a [delete marker](#) for the object.
- If the object version is protected with governance retention mode and you have the `s3:BypassGovernanceRetention` permission, you can bypass the protection and permanently delete the version. For more information, see [Bypassing governance mode](#).
- If the object version is protected by a legal hold, then a permanent DELETE request can result in an Access Denied (403 Forbidden) error. To permanently delete the object version, you must remove the legal hold on the object version. To remove a legal hold, you must have the `s3:PutObjectLegalHold` permission. For more information about removing a legal hold, see [Configuring S3 Object Lock](#).

VPC endpoint policies

If you're accessing Amazon S3 by using a virtual private cloud (VPC) endpoint, make sure that the VPC endpoint policy isn't blocking you from accessing your Amazon S3 resources. By default, the VPC endpoint policy allows all requests to Amazon S3. You can also configure the VPC endpoint policy to restrict certain requests. For information about how to check your VPC endpoint policy, see the following resources:

- [the section called "Access denied due to a VPC endpoint policy – implicit denial"](#)
- [the section called "Access denied due to a VPC endpoint policy – explicit denial"](#)
- [Control access to VPC endpoints by using endpoint policies](#) in the *AWS PrivateLink Guide*

AWS Organizations policies

If your AWS account belongs to an organization, AWS Organizations policies can block you from accessing Amazon S3 resources. By default, AWS Organizations policies don't block any requests to Amazon S3. However, make sure that your AWS Organizations policies haven't been configured to block access to S3 buckets. For instructions on how to check your AWS Organizations policies, see the following resources:

- [the section called "Access denied due to a Service Control Policy – implicit denial"](#)
- [the section called "Access denied due to a Service Control Policy – explicit denial"](#)
- [the section called "Access denied due to a resource control policy – explicit denial"](#)
- [Listing all policies](#) in the *AWS Organizations User Guide*

Additionally, if you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can unlock the bucket by launching a privileged session for the member account in IAM. Once you launch a privileged session, you can delete the misconfigured bucket policy to regain access to the bucket. For more information, see [Perform a privileged task on an AWS Organizations member account](#) in the *AWS Identity and Access Management User Guide*.

Access point settings

If you receive an Access Denied (403 Forbidden) error while making requests through Amazon S3 access points, you might need to check the following:

- The configurations for your access points
- The IAM user policy that's used for your access points
- The bucket policy that's used to manage or configure your cross-account access points

Access point configurations and policies

- When you create an access point, you can choose to designate **Internet** or **VPC** as the network origin. If the network origin is set to VPC only, Amazon S3 will reject any requests made to the access point that don't originate from the specified VPC. To check the network origin of your access point, see [Creating access points restricted to a virtual private cloud](#).
- With access points, you can also configure custom Block Public Access settings, which work similarly to the Block Public Access settings at the bucket or account level. To check your custom Block Public Access settings, see [Managing public access to access points](#).

- To make successful requests to Amazon S3 by using access points, make sure that the requester has the necessary IAM permissions. For more information, see [Configuring IAM policies for using access points](#).
- If the request involves cross-account access points, make sure that the bucket owner has updated the bucket policy to authorize requests from the access point. For more information, see [Granting permissions for cross-account access points](#).

If the Access Denied (403 Forbidden) error still persists after checking all the items in this topic, [retrieve your Amazon S3 request ID](#) and contact Support for additional guidance.

AWS managed policies for Amazon S3

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

AWS managed policy: AmazonS3FullAccess

You can attach the AmazonS3FullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon S3.

To view the permissions for this policy, see [AmazonS3FullAccess](#) in the AWS Management Console.

AWS managed policy: AmazonS3ReadOnlyAccess

You can attach the AmazonS3ReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon S3.

To view the permissions for this policy, see [AmazonS3ReadOnlyAccess](#) in the AWS Management Console.

AWS managed policy: AmazonS3ObjectLambdaExecutionRolePolicy

Provides AWS Lambda functions the required permissions to send data to S3 Object Lambda when requests are made to an S3 Object Lambda access point. Also grants Lambda permissions to write to Amazon CloudWatch logs.

To view the permissions for this policy, see [AmazonS3ObjectLambdaExecutionRolePolicy](#) in the AWS Management Console.

AWS managed policy: S3UnlockBucketPolicy

If you incorrectly configured your bucket policy for a member account to deny all users access to your S3 bucket, you can use this AWS managed policy (S3UnlockBucketPolicy) to unlock the bucket. For more information on how to remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket, see [Perform a privileged task on an AWS Organizations member account](#) in the *AWS Identity and Access Management User Guide*.

Amazon S3 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon S3 since this service began tracking these changes.

Change	Description	Date
Amazon S3 added S3UnlockBucketPolicy	Amazon S3 added a new AWS-managed policy called S3UnlockBucketPolicy to unlock a bucket and remove a misconfigured bucket policy that denies all principals from accessing an Amazon S3 bucket.	November 1, 2024
Amazon S3 added Describe permissions to AmazonS3ReadOnlyAccess	Amazon S3 added s3:Describe* permissions	August 11, 2023

Change	Description	Date
	to AmazonS3ReadonlyAccess .	
Amazon S3 added S3 Object Lambda permissions to AmazonS3FullAccess and AmazonS3ReadonlyAccess	Amazon S3 updated the AmazonS3FullAccess and AmazonS3ReadonlyAccess policies to include permissions for S3 Object Lambda.	September 27, 2021
Amazon S3 added AmazonS3ObjectLambdaExecutionRolePolicy	Amazon S3 added a new AWS-managed policy called AmazonS3ObjectLambdaExecutionRolePolicy that provides Lambda functions permissions to interact with S3 Object Lambda and write to CloudWatch logs.	August 18, 2021
Amazon S3 started tracking changes	Amazon S3 started tracking changes for its AWS managed policies.	August 18, 2021

Managing access to shared datasets with access points

Amazon S3 access points simplify data access for any AWS service or customer application that stores data in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations, such as `GetObject` and `PutObject`. Each access point has distinct permissions and network controls that S3 applies for any request that is made through that access point. Each access point enforces a customized access point policy that works in conjunction with the bucket policy that is attached to the underlying bucket. You can configure any access point to accept requests only from a virtual private cloud (VPC) to restrict Amazon S3 data access to a private network. You can also configure custom block public access settings for each access point.

Note

- You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see [Access point compatibility](#).
- Access points work with some, but not all, AWS services and features. For example, you can't configure Cross-Region Replication to operate through an access point. For a complete list of AWS services that are compatible with S3 access points, see [Access point compatibility](#).

The topics in this section explain how to work with Amazon S3 access points. For information about working with buckets, see [Buckets overview](#). For information about working with objects, see [Amazon S3 objects overview](#).

Topics

- [Access points naming rules, restrictions, and limitations](#)
- [Referencing access points with ARNs, access point aliases, or virtual-hosted-style URLs](#)
- [Access point compatibility](#)
- [Configuring IAM policies for using access points](#)
- [Monitoring and logging access points](#)
- [Creating an access point](#)
- [Managing your Amazon S3 access points](#)
- [Using Amazon S3 access points](#)

Access points naming rules, restrictions, and limitations

Access points are named network endpoints attached to a bucket to simplify managing data. When you create an access point you choose a name and the AWS Region to create it in. The following topics provide information about access point naming rules and restrictions and limitations.

Topics

- [Naming rules for Amazon S3 access points](#)

- [Restrictions and limitations for access points](#)

Naming rules for Amazon S3 access points

When you create an access point you choose its name and the AWS Region to create it in. Unlike general purpose buckets access point names do not need to be unique across AWS accounts or AWS Regions. The same AWS account may create access points with the same name in different AWS Regions or two different AWS accounts may use the same access point name. However, within a single AWS Region an AWS account may not have two identically named access points.

 **Note**

If you choose to publicize your access point name, avoid including sensitive information in the access point name. Access point names are published in a publicly accessible database known as the Domain Name System (DNS).

Access point names must be DNS-compliant and must meet the following conditions:

- Must be unique within a single AWS account and AWS Region
- Must begin with a number or lowercase letter
- Must be between 3 and 50 characters long
- Can't begin or end with a hyphen (-)
- Can't contain underscores (_), uppercase letters, spaces, or periods (.)
- Can't end with the suffix -s3alias. This suffix is reserved for access point alias names. For more information, see [Access point aliases](#).

Restrictions and limitations for access points

Amazon S3 access points have the following restrictions and limitations:

- Each access point is associated with exactly one bucket, which you must specify when you create the access point. After you create an access point, you can't associate it with a different bucket. However, you can delete an access point, and then create another one with the same name and associate that new access point with a different bucket.
- After you create an access point, you can't change its virtual private cloud (VPC) configuration.

- Access point policies are limited to 20 KB in size.
- You can create a maximum of 10,000 access points per AWS account per AWS Region. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see [AWS service quotas](#) in the *AWS General Reference*.
- You can't use an access point as a destination for S3 Replication. For more information about replication, see [Replicating objects within and across Regions](#).
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- You can address access points only by using virtual-host-style URLs. For more information about virtual-host-style addressing, see [Accessing an Amazon S3 bucket](#).
- API operations that control access point functionality (for example, PutAccessPoint and GetAccessPointPolicy) don't support cross-account calls.
- You must use AWS Signature Version 4 when making requests to an access point by using the REST APIs. For more information about authenticating requests, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.
- Access points only support requests over HTTPS. Amazon S3 will automatically respond with an HTTP redirect for any requests made via HTTP, to upgrade the request to HTTPS.
- Access points don't support anonymous access.
- Cross-account access points don't grant you access to data until you are granted permissions from the bucket owner. The bucket owner always retains ultimate control over access to the data and must update the bucket policy to authorize requests from the cross-account access point. To view a bucket policy example, see [Configuring IAM policies for using access points](#).
- In AWS Regions where you have more than 1,000 access points, you can't search for an access point by name in the Amazon S3 console.
- When you're viewing a cross-account access point in the Amazon S3 console, the **Access** column displays **Unknown**. The Amazon S3 console can't determine if public access is granted for the associated bucket and objects. Unless you require a public configuration for a specific use case, we recommend that you and the bucket owner block all public access to the access point and the bucket. For more information, see [Blocking public access to your Amazon S3 storage](#).

Referencing access points with ARNs, access point aliases, or virtual-hosted-style URIs

After you create an access point you can use these endpoints to perform a number of operations. When referring to an access point you can use the Amazon Resource Names (ARNs), access point alias, or virtual-hosted-style URI.

Topics

- [Access point ARNs](#)
- [Access point aliases](#)
- [Virtual-hosted-style URI](#)

Access point ARNs

Access points have Amazon Resource Names (ARNs). Access point ARNs are similar to bucket ARNs, but they are explicitly typed and encode the access point's AWS Region and the AWS account ID of the access point's owner. For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

Access point ARNs use the following format:

```
arn:aws:s3:region:account-id:accesspoint/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test` represents the access point named `test`, owned by account `123456789012` in the Region `us-west-2`.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/*` represents all access points under account `123456789012` in the Region `us-west-2`.

ARNs for objects accessed through an access point use the following format:

```
arn:aws:s3:region:account-id:accesspoint/access-point-name/object/resource
```

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01` represents the object `unit-01`, accessed through the access point named `test`, owned by account `123456789012` in the Region `us-west-2`.

- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/*` represents all objects for the access point named `test`, in account `123456789012` in the Region `us-west-2`.
- `arn:aws:s3:us-west-2:123456789012:accesspoint/test/object/unit-01/finance/*` represents all objects under prefix `unit-01/finance/` for the access point named `test`, in account `123456789012` in the Region `us-west-2`.

Access point aliases

When you create an access point, Amazon S3 automatically generates an alias that you can use instead of an Amazon S3 bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for access point data plane operations. For a list of these operations, see [Access point compatibility](#).

An access point alias name is created within the same namespace as an Amazon S3 bucket. This alias name is automatically generated and cannot be changed. An access point alias name meets all the requirements of a valid Amazon S3 bucket name and consists of the following parts:

access point prefix-metadata-s3alias

 **Note**

The `-s3alias` suffix is reserved for access point alias names and can't be used for bucket or access point names. For more information about Amazon S3 bucket-naming rules, see [General purpose bucket naming rules](#).

Access point alias use cases and limitations

When adopting access points, you can use access point alias names without requiring extensive code changes.

When you create an access point, Amazon S3 automatically generates an access point alias name, as shown in the following example. To run this command, replace the `user input placeholders` with your own information.

```
aws s3control create-access-point --bucket amzn-s3-demo-bucket1 --name my-access-point
--account-id 111122223333{
    "AccessPointArn":  
        "arn:aws:s3:region:111122223333:accesspoint/my-access-point",
```

```
        "Alias": "my-access-point-aqfqprnstan7aefdfbarligizwgyfouse1a-s3alias"  
    }
```

You can use this access point alias name instead of an Amazon S3 bucket name in any data plane operation. For a list of these operations, see [Access point compatibility](#).

The following AWS CLI example for the get-object command uses the bucket's access point alias to return information about the specified object. To run this command, replace the *user input placeholders* with your own information.

```
aws s3api get-object --bucket my-access-point-aqfqprnstan7aefdfbarligizwgyfouse1a-  
s3alias --key dir/my_data.rtf my_data.rtf  
  
{  
    "AcceptRanges": "bytes",  
    "LastModified": "2020-01-08T22:16:28+00:00",  
    "ContentLength": 910,  
    "ETag": "\"00751974dc146b76404bb7290f8f51bb\"",  
    "VersionId": "null",  
    "ContentType": "text/rtf",  
    "Metadata": {}  
}
```

Access point alias limitations

- Aliases cannot be configured by customers.
- Aliases cannot be deleted or modified or disabled on an access point.
- You can use this access point alias name instead of an Amazon S3 bucket name in some data plane operations. For a list of these operations, see [Access point compatibility with S3 operations](#).
- You can't use an access point alias name for Amazon S3 control plane operations. For a list of Amazon S3 control plane operations, see [Amazon S3 Control](#) in the *Amazon Simple Storage Service API Reference*.
- You can't use S3 access point aliases as the source or destination for **Move** operations in the Amazon S3 console.
- Aliases cannot be used in AWS Identity and Access Management (IAM) policies.
- Aliases cannot be used as a logging destination for S3 server access logs.
- Aliases cannot be used as a logging destination for AWS CloudTrail logs.

- Amazon SageMaker GroundTruth does not support access point aliases.

Virtual-hosted-style URI

Access points only support virtual-host-style addressing. In a virtual-hosted-style URI, the access point name, AWS account, and AWS Region is part of the domain name in the URL. For more information about virtual hosting, see [Virtual hosting of buckets](#).

Virtual-hosted-style URI for access points use the following format:

```
https://access-point-name-account-id.s3-accesspoint.region.amazonaws.com
```

Note

- If your access point name includes dash (-) characters, include the dashes in the URL and insert another dash before the account ID. For example, to use an access point named *finance-docs* owned by account *123456789012* in the Region *us-west-2*, the appropriate URL would be `https://finance-docs-123456789012.s3-accesspoint.us-west-2.amazonaws.com`.
- S3 access points don't support access through HTTP. Access points support only secure access through HTTPS.

Access point compatibility

You can use access points to access a bucket using the following subset of Amazon S3 APIs. All the operations listed below can accept either access point ARNs or access point aliases.

For examples of using access points to perform operations on objects, see [Using Amazon S3 access points](#).

Configuring IAM policies for using access points

Amazon S3 access points support AWS Identity and Access Management (IAM) resource policies that allow you to control the use of the access point by resource, user, or other conditions. For an application or user to be able to access objects through an access point, both the access point and the underlying bucket must permit the request.

Important

Adding an S3 access point to a bucket doesn't change the bucket's behavior when the bucket is accessed directly through the bucket's name or Amazon Resource Name (ARN). All existing operations against the bucket will continue to work as before. Restrictions that you include in an access point policy apply only to requests made through that access point.

When you're using IAM resource policies, make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide recommendations to help you author policies that are functional and conform to security best practices.

To learn more about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

Access point policy examples

The following examples demonstrate how to create IAM policies to control requests made through an access point.

Note

Permissions granted in an access point policy are effective only if the underlying bucket also allows the same access. You can accomplish this in two ways:

1. **(Recommended)** Delegate access control from the bucket to the access point, as described in [Delegating access control to access points](#).

2. Add the same permissions contained in the access point policy to the underlying bucket's policy. The Example 1 access point policy example demonstrates how to modify the underlying bucket policy to allow the necessary access.

Example 1 – Access point policy grant

The following access point policy grants IAM user *Jane* in account *123456789012* permissions to GET and PUT objects with the prefix *Jane/* through the access point *my-access-point* in account *123456789012*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Jane"  
            },  
            "Action": ["s3:GetObject", "s3:PutObject"],  
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/  
object/Jane/*"  
        }  
    ]  
}
```

Note

For the access point policy to effectively grant access to *Jane*, the underlying bucket must also allow the same access to *Jane*. You can delegate access control from the bucket to the access point as described in [Delegating access control to access points](#). Or, you can add the following policy to the underlying bucket to grant the necessary permissions to Jane. Note that the Resource entry differs between the access point and bucket policies.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Jane"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:us-west-2:123456789012:bucket/janebucket/  
object/*"  
        }  
    ]  
}
```

```
        },
        "Action": ["s3:GetObject", "s3:PutObject"],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/Jane/*"
    ],
}
```

Example 2 – Access point policy with tag condition

The following access point policy grants IAM user *Mateo* in account *123456789012* permissions to GET objects through the access point *my-access-point* in the account *123456789012* that have the tag key *data* set with a value of *finance*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Mateo"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point/object/*",
            "Condition": {
                "StringEquals": {
                    "s3:ExistingObjectTag/data": "finance"
                }
            }
        }
    ]
}
```

Example 3 – Access point policy that allows bucket listing

The following access point policy allows IAM user Arnav in the account *123456789012* permission to view the objects contained in the bucket underlying the access point *my-access-point* in the account *123456789012*.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": "arn:aws:iam::123456789012:user/Arnav"  
    },  
    "Action": "s3>ListBucket",  
    "Resource": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-access-point"  
}  
}]  
}
```

Example 4 – Service control policy

The following service control policy requires all new access points to be created with a virtual private cloud (VPC) network origin. With this policy in place, users in your organization can't create new access points that are accessible from the internet.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Action": "s3>CreateAccessPoint",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:AccessPointNetworkOrigin": "VPC"  
                }  
            }  
        }  
    ]  
}
```

Example 5 – Bucket policy to limit S3 operations to VPC network origins

The following bucket policy limits access to all S3 object operations for the bucket *amzn-s3-demo-bucket* to access points with a VPC network origin.

Important

Before using a statement like the one shown in this example, make sure that you don't need to use features that aren't supported by access points, such as Cross-Region Replication.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3:AbortMultipartUpload",  
                "s3:BypassGovernanceRetention",  
                "s3:DeleteObject",  
                "s3:DeleteObjectTagging",  
                "s3:DeleteObjectVersion",  
                "s3:DeleteObjectVersionTagging",  
                "s3:GetObject",  
                "s3:GetObjectAcl",  
                "s3:GetObjectLegalHold",  
                "s3:GetObjectRetention",  
                "s3:GetObjectTagging",  
                "s3:GetObjectVersion",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging",  
                "s3>ListMultipartUploadParts",  
                "s3:PutObject",  
                "s3:PutObjectAcl",  
                "s3:PutObjectLegalHold",  
                "s3:PutObjectRetention",  
                "s3:PutObjectTagging",  
                "s3:PutObjectVersionAcl",  
                "s3:PutObjectVersionTagging",  
                "s3:RestoreObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:AccessPointNetworkOrigin": "VPC"  
                }  
            }  
        }  
    ]  
}
```

Condition keys

S3 access points have condition keys that you can use in IAM policies to control access to your resources. The following condition keys represent only part of an IAM policy. For full policy examples, see [Access point policy examples](#), the section called “[Delegating access control to access points](#)”, and the section called “[Granting permissions for cross-account access points](#)”.

s3:DataAccessPointArn

This example shows a string that you can use to match on an access point ARN. The following example matches all access points for AWS account [123456789012](#) in Region [us-west-2](#):

```
"Condition" : {  
    "StringLike": {  
        "s3:DataAccessPointArn": "arn:aws:s3:us-west-2:123456789012:accesspoint/*"  
    }  
}
```

s3:DataAccessPointAccount

This example shows a string operator that you can use to match on the account ID of the owner of an access point. The following example matches all access points that are owned by the AWS account [123456789012](#).

```
"Condition" : {  
    "StringEquals": {  
        "s3:DataAccessPointAccount": "123456789012"  
    }  
}
```

s3:AccessPointNetworkOrigin

This example shows a string operator that you can use to match on the network origin, either Internet or VPC. The following example matches only access points with a VPC origin.

```
"Condition" : {  
    "StringEquals": {  
        "s3:AccessPointNetworkOrigin": "VPC"  
    }  
}
```

For more information about using condition keys with Amazon S3, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Delegating access control to access points

You can delegate access control for a bucket to the bucket's access points. The following example bucket policy allows full access to all access points that are owned by the bucket owner's account. Thus, all access to this bucket is controlled by the policies attached to its access points. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket.

Example 6 – Bucket policy that delegates access control to access points

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : "*",  
            "Resource" : [ "Bucket ARN", "Bucket ARN/*"],  
            "Condition": {  
                "StringEquals" : { "s3:DataAccessPointAccount" : "Bucket owner's account ID" }  
            }  
        }  
    ]  
}
```

Granting permissions for cross-account access points

To create an access point to a bucket that's owned by another account, you must first create the access point by specifying the bucket name and account owner ID. Then, the bucket owner must update the bucket policy to authorize requests from the access point. Creating an access point is similar to creating a DNS CNAME in that the access point doesn't provide access to the bucket contents. All bucket access is controlled by the bucket policy. The following example bucket policy allows GET and LIST requests on the bucket from an access point that's owned by a trusted AWS account.

Replace **Bucket ARN** with the ARN of the bucket.

Example 7 – Bucket policy delegating permissions to another AWS account

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : ["s3:GetObject","s3>ListBucket"],  
            "Resource" : [ "Bucket ARN", "Bucket ARN/*"],  
            "Condition": {  
                "StringEquals" : { "s3>DataAccessPointAccount" : "Access point owner's  
account ID" }  
            }  
        }]  
    }  
}
```

Monitoring and logging access points

Amazon S3 logs requests made through access points and requests made to the API operations that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`. To monitor and manage usage patterns, you can also configure Amazon CloudWatch Logs request metrics for access points.

Topics

- [CloudWatch request metrics](#)
- [Request logs](#)

CloudWatch request metrics

To understand and improve the performance of applications that are using access points, you can use CloudWatch for Amazon S3 request metrics. Request metrics help you monitor Amazon S3 requests to quickly identify and act on operational issues.

By default, request metrics are available at the bucket level. However, you can define a filter for request metrics using a shared prefix, object tags, or an access point. When you create an access point filter, the request metrics configuration includes requests to the access point that you specify.

You can receive metrics, set alarms, and access dashboards to view real-time operations performed through this access point.

You must opt in to request metrics by configuring them in the console or by using the Amazon S3 API. Request metrics are available at 1-minute intervals after some latency for processing. Request metrics are billed at the same rate as CloudWatch custom metrics. For more information, see [Amazon CloudWatch pricing](#).

To create a request metrics configuration that filters by access point, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

Request logs

You can log requests made through access points and requests made to the APIs that manage access points, such as `CreateAccessPoint` and `GetAccessPointPolicy`, by using server access logging and AWS CloudTrail.

CloudTrail log entries for requests made through access points include the access point ARN in the resources section of the log.

For example, suppose you have the following configuration:

- A bucket named *amzn-s3-demo-bucket1* in Region *us-west-2* that contains an object named *my-image.jpg*
- An access point named *my-bucket-ap* that is associated with *amzn-s3-demo-bucket1*
- An AWS account ID of *123456789012*

The following example shows the resources section of a CloudTrail log entry for the preceding configuration:

```
"resources": [  
    {"type": "AWS::S3::Object",  
     "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1/my-image.jpg"  
    },  
    {"accountId": "123456789012",  
     "type": "AWS::S3::Bucket",  
     "ARN": "arn:aws:s3:::amzn-s3-demo-bucket1"  
    },  
]
```

```
{"accountId": "123456789012",
 "type": "AWS::S3::AccessPoint",
 "ARN": "arn:aws:s3:us-west-2:123456789012:accesspoint/my-bucket-ap"
}
]
```

For more information about S3 Server Access Logs, see [Logging requests with server access logging](#). For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the [AWS CloudTrail User Guide](#).

Creating an access point

You can create S3 access points by using the AWS Management Console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

By default, you can create up to 10,000 access points per Region for each of your AWS accounts. If you need more than 10,000 access points for a single account in a single Region, you can request a service quota increase. For more information about service quotas and requesting an increase, see [AWS Service Quotas](#) in the *AWS General Reference*.

Topics

- [Creating access points](#)
- [Creating access points restricted to a virtual private cloud](#)
- [Managing public access to access points](#)

Creating access points

An access point is associated with exactly one Amazon S3 bucket. If you want to use a bucket in your AWS account, you must first create a bucket. For more information about creating buckets, see [Creating, configuring, and working with Amazon S3 buckets](#).

You can also create a cross-account access point that's associated with a bucket in another AWS account, as long as you know the bucket name and the bucket owner's account ID. However, creating cross-account access points doesn't grant you access to data in the bucket until you are granted permissions from the bucket owner. The bucket owner must grant the access point owner's account (your account) access to the bucket through the bucket policy. For more information, see [Granting permissions for cross-account access points](#).

Using the S3 console

To create an access point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create an access point. The access point must be created in the same Region as the associated bucket.
3. In the left navigation pane, choose **Access Points**.
4. On the **Access Points** page, choose **Create access point**.
5. In the **Access point name** field, enter the name for the access point. For more information about naming access points, see [Naming rules for Amazon S3 access points](#).
6. For **Bucket name**, specify the S3 bucket that you want to use with the access point.

To use a bucket in your account, choose **Choose a bucket in this account**, and enter or browse for the bucket name.

To use a bucket in a different AWS account, choose **Specify a bucket in another account**, and enter the AWS account ID and name of the bucket.

 **Note**

If you're using a bucket in a different AWS account, the bucket owner must update the bucket policy to authorize requests from the access point. For an example bucket policy, see [Granting permissions for cross-account access points](#).

7. Choose a **Network origin**, either **Internet** or **virtual private cloud (VPC)**. If you choose **virtual private cloud (VPC)**, enter the **VPC ID** that you want to use with the access point.

For more information about network origins for access points, see [Creating access points restricted to a virtual private cloud](#).

8. Under **Block Public Access settings for this Access Point**, select the block public access settings that you want to apply to the access point. All block public access settings are enabled by default for new access points. We recommend that you keep all settings enabled unless you know that you have a specific need to disable any of them.

Note

After you create an access point, you can't change its block public access settings.

For more information about using Amazon S3 Block Public Access with access points, see [Managing public access to access points](#).

9. (Optional) Under **Access Point policy - optional**, specify the access point policy. Before you save your policy, make sure to resolve any security warnings, errors, general warnings, and suggestions. For more information about specifying an access point policy, see [Access point policy examples](#).
10. Choose **Create access point**.

Using the AWS CLI

The following example command creates an access point named *example-ap* for the bucket *amzn-s3-demo-bucket* in the account *111122223333*. To create the access point, you send a request to Amazon S3 that specifies the following:

- The access point name. For information about naming rules, see [the section called “Naming rules for Amazon S3 access points”](#).
- The name of the bucket that you want to associate the access point with.
- The account ID for the AWS account that owns the access point.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --  
bucket amzn-s3-demo-bucket
```

When you're creating an access point by using a bucket in a different AWS account, include the `--bucket-account-id` parameter. The following example command creates an access point in the AWS account *111122223333*, using the bucket *amzn-s3-demo-bucket2*, which is in the AWS account *44445556666*.

```
aws s3control create-access-point --name example-ap --account-id 111122223333 --  
bucket amzn-s3-demo-bucket --bucket-account-id 44445556666
```

Using the REST API

You can use the REST API to retrieve objects from Amazon S3. For more information, see [CreateAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Creating access points restricted to a virtual private cloud

When you create an access point, you can choose to make the access point accessible from the internet, or you can specify that all requests made through that access point must originate from a specific virtual private cloud (VPC). An access point that's accessible from the internet is said to have a network origin of Internet. It can be used from anywhere on the internet, subject to any other access restrictions in place for the access point, underlying bucket, and related resources, such as the requested objects. An access point that's only accessible from a specified VPC has a network origin of VPC, and Amazon S3 rejects any request made to the access point that doesn't originate from that VPC.

 **Important**

You can only specify an access point's network origin when you create the access point. After you create the access point, you can't change its network origin.

To restrict an access point to VPC-only access, you include the `VpcConfiguration` parameter with the request to create the access point. In the `VpcConfiguration` parameter, you specify the VPC ID that you want to be able to use the access point. If a request is made through the access point, the request must originate from the VPC or Amazon S3 will reject it.

You can retrieve an access point's network origin using the AWS CLI, AWS SDKs, or REST APIs. If an access point has a VPC configuration specified, its network origin is VPC. Otherwise, the access point's network origin is Internet.

Example

Example: Create an access point that's restricted to VPC access

The following example creates an access point named `example-vpc-ap` for bucket `amzn-s3-demo-bucket` in account 123456789012 that allows access only from the `vpc-1a2b3c` VPC. The example then verifies that the new access point has a network origin of VPC.

AWS CLI

```
aws s3control create-access-point --name example-vpc-ap --account-id 123456789012 --bucket amzn-s3-demo-bucket --vpc-configuration VpcId=vpc-1a2b3c
```

```
aws s3control get-access-point --name example-vpc-ap --account-id 123456789012

{
    "Name": "example-vpc-ap",
    "Bucket": "amzn-s3-demo-bucket",
    "NetworkOrigin": "VPC",
    "VpcConfiguration": {
        "VpcId": "vpc-1a2b3c"
    },
    "PublicAccessBlockConfiguration": {
        "BlockPublicAccls": true,
        "IgnorePublicAccls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "CreationDate": "2019-11-27T00:00:00Z"
}
```

To use an access point with a VPC, you must modify the access policy for your VPC endpoint. VPC endpoints allow traffic to flow from your VPC to Amazon S3. They have access control policies that control how resources within the VPC are allowed to interact with Amazon S3. Requests from your VPC to Amazon S3 only succeed through an access point if the VPC endpoint policy grants access to both the access point and the underlying bucket.

Note

To make resources accessible only within a VPC, make sure to create a [private hosted zone](#) for your VPC endpoint. To use a private hosted zone, [modify your VPC settings](#) so that the [VPC network attributes](#) enableDnsHostnames and enableDnsSupport are set to true.

The following example policy statement configures a VPC endpoint to allow calls to GetObject for a bucket named awsexamplebucket1 and an access point named example-vpc-ap.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::awsexamplebucket1/*",  
                "arn:aws:s3:us-west-2:123456789012:accesspoint/example-vpc-ap/object/*"  
            ]  
        }]  
    }]
```

Note

The "Resource" declaration in this example uses an Amazon Resource Name (ARN) to specify the access point. For more information about access point ARNs, see [Using Amazon S3 access points](#).

For more information about VPC endpoint policies, see [Using endpoint policies for Amazon S3](#) in the *VPC User Guide*.

For a tutorial on creating access points with VPC endpoints, see [Managing Amazon S3 access with VPC endpoints and access points](#).

Managing public access to access points

Amazon S3 access points support independent *block public access* settings for each access point. When you create an access point, you can specify block public access settings that apply to that access point. For any request made through an access point, Amazon S3 evaluates the block public access settings for that access point, the underlying bucket, and the bucket owner's account. If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request.

For more information about the S3 Block Public Access feature, see [Blocking public access to your Amazon S3 storage](#).

Important

- All block public access settings are enabled by default for access points. You must explicitly disable any settings that you don't want to apply to an access point.
- Amazon S3 currently doesn't support changing an access point's block public access settings after the access point has been created.

Example

Example: Create an access point with Custom Block Public Access Settings

This example creates an access point named `example-ap` for bucket `amzn-s3-demo-bucket` in account 123456789012 with non-default Block Public Access settings. The example then retrieves the new access point's configuration to verify its Block Public Access settings.

AWS CLI

```
aws s3control create-access-point --name example-ap --account-id  
123456789012 --bucket amzn-s3-demo-bucket--public-access-block-configuration  
BlockPublicAcls=false,IgnorePublicAcls=false,BlockPublicPolicy=true,RestrictPublicBuckets=t
```

```
aws s3control get-access-point --name example-ap --account-id 123456789012  
  
{  
    "Name": "example-ap",  
    "Bucket": "amzn-s3-demo-bucket",  
    "NetworkOrigin": "Internet",  
    "PublicAccessBlockConfiguration": {  
        "BlockPublicAcls": false,  
        "IgnorePublicAcls": false,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "CreationDate": "2019-11-27T00:00:00Z"  
}
```

Managing your Amazon S3 access points

This section explains how to manage your Amazon S3 access points using the AWS Management Console, AWS Command Line Interface, or REST API.

Note

- You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see [Access point compatibility](#).
- Access points work with some, but not all, AWS services and features. For example, you can't configure Cross-Region Replication to operate through an access point. For a complete list of AWS services that are compatible with S3 access points, see [Access point compatibility](#).

Topics

- [List your access points](#)
- [View details for your access point](#)
- [Delete your access point](#)

List your access points

This section explains how to list your access points using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.

4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.

Using the AWS CLI

The following `list-access-points` example command shows how you can use the AWS CLI to list your access points.

The following command lists access points for AWS account `111122223333`.

```
aws s3control list-access-points --account-id 111122223333
```

The following command lists access points for AWS account `111122223333` that are attached to bucket `amzn-s3-demo-bucket`.

```
aws s3control list-access-points --account-id 111122223333 --bucket amzn-s3-demo-bucket
```

For more information and examples, see [list-access-points](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see [ListAccessPoints](#) in the *Amazon Simple Storage Service API Reference*.

View details for your access point

This section explains how to view details for your access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To view details for your access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.

4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Select the **Properties** tab to view the access point bucket, account ID, AWS Region, creation date, network origin, S3 URI, ARN, and access point alias for the selected access point.
7. Select the **Permissions** tab to view the Block Public Access settings and access point policy for the selected access point.

 **Note**

You can't change the Block Public Access settings for an access point after the access point is created.

Using the AWS CLI

The following get-access-point example command shows how you can use the AWS CLI to view details for your access point.

The following command lists details for the access point *my-access-point* for AWS account **111122223333**.

```
aws s3control get-access-point --name my-access-point --account-id 111122223333
```

Example output:

```
{  
    "Name": "my-access-point",  
    "Bucket": "amzn-s3-demo-bucket",  
    "NetworkOrigin": "Internet",  
    "PublicAccessBlockConfiguration": {  
        "BlockPublicAcls": true,  
        "IgnorePublicAcls": true,  
        "BlockPublicPolicy": true,  
        "RestrictPublicBuckets": true  
    },  
    "CreationDate": "2016-08-29T22:57:52Z",  
    "Alias": "my-access-point-u1ny6bhm7moymqx8cuon8o1g4mwikuse2a-s3alias",  
    "AccessPointArn": "arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point",  
    "Endpoints": {
```

```
        "ipv4": "s3-accesspoint.AWS Region.amazonaws.com",
        "fips": "s3-accesspoint-fips.AWS Region.amazonaws.com",
        "fips_dualstack": "s3-accesspoint-fips.dualstack.AWS Region.amazonaws.com",
        "dualstack": "s3-accesspoint.dualstack.AWS Region.amazonaws.com"
    },
    "BucketAccountId": "111122223333"
}
```

For more information and examples, see [get-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see [GetAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Delete your access point

This section explains how to delete your access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete for your access points in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. From the **Access Point** page, select **Delete** to delete the access point you've selected.
7. To confirm deletion, type the name of the access point and choose **Delete**.

Using the AWS CLI

The following `delete-access-point` example command shows how you can use the AWS CLI to delete your access point.

The following command deletes the access point *my-access-point* for AWS account **111122223333**.

```
aws s3control delete-access-point --name my-access-point --account-id 111122223333
```

For more information and examples, see [delete-access-point](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to view details for your access point. For more information, see [DeleteAccessPoint](#) in the *Amazon Simple Storage Service API Reference*.

Using Amazon S3 access points

The following examples demonstrate how to use access points with compatible operations in Amazon S3.

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

You can only use access points to perform operations on objects. You can't use access points to perform other Amazon S3 operations, such as modifying or deleting buckets. For a complete list of S3 operations that support access points, see [Access point compatibility](#).

Topics

- [List objects through an access point](#)
- [Download an object through an access point](#)
- [Configure access control lists \(ACLs\) through an access point](#)
- [Upload an object through an access point](#)
- [Add a tag-set through an access point](#)
- [Delete an object through an access point](#)

List objects through an access point

This section explains how to list your objects through an access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To list your objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, you can view the name of objects that you want to access through the access point. While you're using the access point, you can only perform the object operations that are allowed by the access point permissions.

Note

- The console view always shows all objects in the bucket. Using an access point as described in this procedure restricts the operations you can perform on those objects, but not whether you can see that they exist in the bucket.
- The AWS Management Console doesn't support using virtual private cloud (VPC) access points to access bucket resources. To access bucket resources from a VPC access point, use the AWS CLI, AWS SDKs, or Amazon S3 REST APIs.

Using the AWS CLI

The following `list-objects-v2` example command shows how you can use the AWS CLI to list your object through an access point.

The following command lists objects for AWS account **111122223333** using access point **my-access-point**.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [list-access-points](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to list your access points. For more information, see [ListObjectsV2](#) in the *Amazon Simple Storage Service API Reference*.

Download an object through an access point

This section explains how to download an object through an access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To download an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of object that you want to download.
7. Choose **Download**.

Using the AWS CLI

The following get-object example command shows how you can use the AWS CLI to download an object through an access point.

The following command downloads the object puppy.jpg for AWS account **111122223333** using access point *my-access-point*. You must include an outfile, which is a file name for the downloaded object, such as *my_downloaded_image.jpg*.

```
aws s3api get-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg my_downloaded_image.jpg
```

Note

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [get-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to download an object through an access point. For more information, see [GetObject](#) in the *Amazon Simple Storage Service API Reference*.

Configure access control lists (ACLs) through an access point

This section explains how to configure ACLs through an access point using the AWS Management Console, AWS Command Line Interface, or REST API. For more information about ACLs, see [Access control list \(ACL\) overview](#).

Using the S3 console

To configure ACLs through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.

3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to configure an ACL for.
7. Under the **Permissions** tab, select **Edit** to configure the object ACL.

 **Note**

Amazon S3 currently doesn't support changing an access point's block public access settings after the access point has been created.

Using the AWS CLI

The following `put-object-acl` example command shows how you can use the AWS CLI to configure access permissions through an access point using an ACL.

The following command applies an ACL to an existing object `puppy.jpg` through an access point owned by AWS account **111122223333**.

```
aws s3api put-object-acl --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --acl private
```

 **Note**

S3 automatically generate access point aliases for all access points and these aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object-acl](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to configure access permissions through an access point using an ACL. For more information, see [PutObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.

Upload an object through an access point

This section explains how to upload an object through an access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To upload an object through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select **Upload**.
7. Drag and drop files and folders you want to upload here, or choose **Add files** or **Add folder**.

 **Note**

The maximum size of a file that you can upload by using the Amazon S3 console is 160 GB. To upload a file larger than 160 GB, use the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

8. To change access control list permissions, choose **Permissions**.
9. Under **Access control list (ACL)**, edit the permissions.

For information about object access permissions, see [Using the S3 console to set ACL permissions for an object](#). You can grant read access to your objects to the public (everyone in the world) for all of the files that you're uploading. However, we recommend not changing the default setting for public read access. Granting public read access is applicable to a small subset of use cases, such as when buckets are used for websites. You can always change the object permissions after you upload the object.

10. To configure other additional properties, choose **Properties**.
11. Under **Storage class**, choose the storage class for the files that you're uploading.

For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

12. To update the encryption settings for your objects, under **Server-side encryption settings**, do the following.
 - a. Choose **Specify an encryption key**.
 - b. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
 - c. If you chose **Override bucket settings for default encryption**, you must configure the following encryption settings.
 - To encrypt the uploaded files by using keys that are managed by Amazon S3, choose **Amazon S3 managed key (SSE-S3)**.

For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

- To encrypt the uploaded files by using keys stored in AWS Key Management Service (AWS KMS), choose **AWS Key Management Service key (SSE-KMS)**. Then choose one of the following options for **AWS KMS key**:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠ Important

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

13. To use additional checksums, choose **On**. Then for **Checksum function**, choose the function that you would like to use. Amazon S3 calculates and stores the checksum value after it receives the entire object. You can use the **Precalculated value** box to supply a precalculated value. If you do, Amazon S3 compares the value that you provided to the value that it calculates. If the two values do not match, Amazon S3 generates an error.

Additional checksums enable you to specify the checksum algorithm that you would like to use to verify your data. For more information about additional checksums, see [Checking object integrity in Amazon S3](#).

14. To add tags to all of the objects that you are uploading, choose **Add tag**. Enter a tag name in the **Key** field. Enter a value for the tag.

Object tagging gives you a way to categorize storage. Each tag is a key-value pair. Key and tag values are case sensitive. You can have up to 10 tags per object. A tag key can be up to 128 Unicode characters in length, and tag values can be up to 255 Unicode characters in length. For more information about object tags, see [Categorizing your storage using tags](#).

15. To add metadata, choose **Add metadata**.

- a. Under **Type**, choose **System defined** or **User defined**.

For system-defined metadata, you can select common HTTP headers, such as **Content-Type** and **Content-Disposition**. For a list of system-defined metadata and information about whether you can add the value, see [System-defined object metadata](#). Any metadata starting with the prefix x-amz-meta- is treated as user-defined metadata. User-defined metadata is stored with the object and is returned when you download the object. Both

the keys and their values must conform to US-ASCII standards. User-defined metadata can be as large as 2 KB. For more information about system-defined and user-defined metadata, see [Working with object metadata](#).

- b. For **Key**, choose a key.
 - c. Type a value for the key.
16. To upload your objects, choose **Upload**.

Amazon S3 uploads your object. When the upload completes, you can see a success message on the **Upload: status** page.

Using the AWS CLI

The following put-object example command shows how you can use the AWS CLI to upload an object through an access point.

The following command uploads the object `puppy.jpg` for AWS account `111122223333` using access point `my-access-point`.

```
aws s3api put-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg --body puppy.jpg
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to upload an object through an access point. For more information, see [PutObject](#) in the *Amazon Simple Storage Service API Reference*.

Add a tag-set through an access point

This section explains how to add a tag-set through an access point using the AWS Management Console, AWS Command Line Interface, or REST API. For more information, see [Categorizing your storage using tags](#).

Using the S3 console

To add a tag-set through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object you wish to add a tag-set to.
7. Under the **Properties** tab, find the **Tags** sub-header and choose **Edit**.
8. Review the objects listed, and choose **Add tag**.
9. Each object tag is a key-value pair. Enter a **Key** and a **Value**. To add another tag, choose **Add Tag**.

You can enter up to 10 tags for an object.

10. Choose **Save changes**.

Using the AWS CLI

The following put-object-tagging example command shows how you can use the AWS CLI to add a tag-set through an access point.

The following command adds a tag-set for existing object puppy.jpg using access point *my-access-point*.

```
aws s3api put-object-tagging --bucket arn:aws:s3:AWS
Region:111122223333:accesspoint/my-access-point --key puppy.jpg --tagging
TagSet=[{Key="animal",Value="true"}]
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [put-object-tagging](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to add a tag-set to an object through an access point. For more information, see [PutObjectTagging](#) in the *Amazon Simple Storage Service API Reference*.

Delete an object through an access point

This section explains how to delete an object through an access point using the AWS Management Console, AWS Command Line Interface, or REST API.

Using the S3 console

To delete an object or objects through an access point in your AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to list access points for.
3. In the navigation pane on the left side of the console, choose **Access Points**.
4. (Optional) Search for access points by name. Only access points in your selected AWS Region will appear here.
5. Choose the name of the access point you want to manage or use.
6. Under the **Objects** tab, select the name of the object or objects you wish to delete.
7. Review the objects listed for deletion, and type *delete* in the confirmation box.
8. Choose **Delete objects**.

Using the AWS CLI

The following delete-object example command shows how you can use the AWS CLI to delete an object through an access point.

The following command deletes the existing object `puppy.jpg` using access point `my-access-point`.

```
aws s3api delete-object --bucket arn:aws:s3:AWS Region:111122223333:accesspoint/my-access-point --key puppy.jpg
```

Note

S3 automatically generate access point aliases for all access points and access point aliases can be used anywhere a bucket name is used to perform object-level operations. For more information, see [Access point aliases](#).

For more information and examples, see [delete-object](#) in the *AWS CLI Command Reference*.

Using the REST API

You can use the REST API to delete an object through an access point. For more information, see [DeleteObject](#) in the *Amazon Simple Storage Service API Reference*.

Managing access with S3 Access Grants

To adhere to the principle of least privilege, you define granular access to your Amazon S3 data based on applications, personas, groups, or organizational units. You can use various approaches to achieve granular access to your data in Amazon S3, depending on the scale and complexity of the access patterns.

The simplest approach for managing access to small-to-medium numbers of datasets in Amazon S3 by AWS Identity and Access Management (IAM) principals is to define [IAM permission policies](#) and [S3 bucket policies](#). This strategy works, so long as the necessary policies fit within the policy size limits of S3 bucket policies (20 KB) and IAM policies (5 KB), and within the [number of IAM principals allowed per account](#).

As your number of datasets and use cases scales, you might require more policy space. An approach that offers significantly more space for policy statements is to use [S3 Access Points](#) as additional

endpoints for S3 buckets, because each access point can have its own policy. You can define quite granular access control patterns, because you can have thousands of access points per AWS Region per account, with a policy up to 20 KB in size for each access point. Although S3 Access Points increases the amount of policy space available, it requires a mechanism for clients to discover the right access point for the right dataset.

A third approach is to implement an [IAM session broker](#) pattern, in which you implement access-decision logic and dynamically generate short-term IAM session credentials for each access session. While the IAM session broker approach supports arbitrarily dynamic permissions patterns and scales effectively, you must build the access-pattern logic.

Instead of using these approaches, you can use S3 Access Grants to manage access to your Amazon S3 data. S3 Access Grants provides a simplified model for defining access permissions to data in Amazon S3 by prefix, bucket, or object. In addition, you can use S3 Access Grants to grant access to both IAM principals and directly to users or groups from your corporate directory.

You commonly define permissions to data in Amazon S3 by mapping users and groups to datasets. You can use S3 Access Grants to define direct access mappings of S3 prefixes to users and roles within Amazon S3 buckets and objects. With the simplified access scheme in S3 Access Grants, you can grant read-only, write-only, or read-write access on a per-S3-prefix basis to both IAM principals and directly to users or groups from a corporate directory. With these S3 Access Grants capabilities, applications can request data from Amazon S3 on behalf of the application's current authenticated user.

When you integrate S3 Access Grants with the [trusted identity propagation](#) feature of AWS IAM Identity Center, your applications can make requests to AWS services (including S3 Access Grants) directly on behalf of an authenticated corporate directory user. Your applications no longer need to first map the user to an IAM principal. Furthermore, because end-user identities are propagated all the way to Amazon S3, auditing which user accessed which S3 object is simplified. You no longer need to reconstruct the relationship between different users and IAM sessions. When you're using S3 Access Grants with IAM Identity Center trusted identity propagation, each [AWS CloudTrail](#) data event for Amazon S3 contains a direct reference to the end user on whose behalf the data was accessed.

For more information about S3 Access Grants, see the following topics.

S3 Access Grants concepts

S3 Access Grants workflow

The S3 Access Grants workflow is:

1. Create an S3 Access Grants instance. See [Working with S3 Access Grants instances](#).
2. Within your S3 Access Grants instance, register locations in your Amazon S3 data, and map these locations to AWS Identity and Access Management (IAM) roles. See [Register a location](#).
3. Create grants for grantees, which give grantees access to your S3 resources. See [Working with grants in S3 Access Grants](#).
4. The grantee requests temporary credentials from S3 Access Grants. See [Request access to Amazon S3 data through S3 Access Grants](#).
5. The grantee accesses the S3 data using those temporary credentials. See [Accessing S3 data using credentials vended by S3 Access Grants](#).

For more information, see [Getting started with S3 Access Grants](#).

S3 Access Grants instances

An *S3 Access Grants instance* is a logical container for individual *grants*. When you create an S3 Access Grants instance, you must specify an AWS Region. Each AWS Region in your AWS account can have one S3 Access Grants instance. For more information, see [Working with S3 Access Grants instances](#).

If you want to use S3 Access Grants to grant access to user and group identities from your corporate directory, you must also associate your S3 Access Grants instance with an AWS IAM Identity Center instance. For more information, see [S3 Access Grants and corporate directory identities](#).

A newly created S3 Access Grants instance is empty. You must register a location in the instance, which can be the S3 default path (`s3://`), a bucket, or a prefix within a bucket. After you register at least one location, you can create access grants that give access to data in this registered location.

Locations

An S3 Access Grants *location* maps buckets or prefixes to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that's accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in the AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the ***amzn-s3-demo-bucket*** is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

- The default S3 location (`s3://`)
- A bucket (for example, `amzn-s3-demo-bucket`) or multiple buckets
- A bucket and a prefix (for example, `amzn-s3-demo-bucket/prefix*`) or multiple prefixes

For the maximum number of locations that you can register in your S3 Access Grants instance, see [S3 Access Grants limitations](#). For more information about registering an S3 Access Grants location, see [Register a location](#).

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. So, no access has been granted yet to any of your S3 data. You can now create access grants to give access. For more information about creating grants, see [Working with grants in S3 Access Grants](#).

Grants

An individual *grant* in an S3 Access Grants instance allows a specific identity—an IAM principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance.

When you create a grant, you don't have to grant access to the entire registered location. You can narrow the grant's scope of access within a location. If the registered location is the default S3 path (`s3://`), you are required to narrow the scope of the grant to a bucket, a prefix within a bucket, or a specific object. If the registered location of the grant is a bucket or a prefix, then you can give access to the entire bucket or prefix, or you can optionally narrow the scope of the grant to a prefix, subprefix, or an object.

In the grant, you also set the access level of the grant to READ, WRITE, or READWRITE.

Suppose you have a grant that gives the corporate directory group `01234567-89ab-cdef-0123-456789abcdef` READ access to the bucket `s3://amzn-s3-demo-bucket/projects/items/*`. Users in this group can have READ access to every object that has an object key name which starts with the prefix `projects/items/` in the bucket named `amzn-s3-demo-bucket`.

For the maximum number of grants that you can create in your S3 Access Grants instance, see [S3 Access Grants limitations](#). For more information about creating grants, see [Create grants](#).

S3 Access Grants temporary credentials

After you create a grant, an authorized application that utilizes the identity specified in the grant can request *just-in-time access credentials*. To do this, the application calls the

[GetDataAdapter](#) S3 API operation. Grantees can use this API operation to request access to the S3 data you have shared with them.

The S3 Access Grants instance evaluates the GetDataAdapter request against the grants that it has. If there is a matching grant for the requestor, S3 Access Grants assumes the IAM role that's associated with the registered location of the matching grant. S3 Access Grants scopes the permissions of the temporary credentials to access only the S3 bucket, prefix, or object that's specified by the grant's scope.

The expiration time of the temporary access credentials defaults to 1 hour, but you can set it to any value from 15 minutes to 12 hours. See the maximum duration session in the [AssumeRole](#) API reference.

How it works

In the following diagram, a default Amazon S3 location with the scope `s3://` is registered with the IAM role `s3ag-location-role`. This IAM role has permissions to perform Amazon S3 actions within the account when its credentials are obtained through S3 Access Grants.

Within this location, two individual access grants are created for two IAM users. The IAM user Bob is granted both READ and WRITE access on the `bob/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. Another IAM role, Alice, is granted only READ access on the `alice/` prefix in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in blue, is defined for Bob to access the prefix `bob/` in the `DOC-BUCKET-EXAMPLE` bucket. A grant, colored in green, is defined for Alice to access the prefix `alice/` in the `DOC-BUCKET-EXAMPLE` bucket.

When it's time for Bob to READ data, the IAM role that's associated with the location that his grant is in calls the S3 Access Grants [GetDataAdapter](#) API operation. If Bob tries to READ any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, the GetDataAdapter request returns a set of temporary IAM session credentials with permission to `s3://DOC-BUCKET-EXAMPLE/bob/*`. Similarly, Bob can WRITE to any S3 prefix or object that starts with `s3://DOC-BUCKET-EXAMPLE/bob/*`, because the grant also allows that.

Similarly, Alice can READ anything that starts with `s3://DOC-BUCKET-EXAMPLE/alice/`. However, if she tries to WRITE anything to any bucket, prefix, or object in `s3://`, she will get an Access Denied (403 Forbidden) error, because there is no grant that gives her WRITE access to any data. In addition, if Alice requests any level of access (READ or WRITE) to data outside of `s3://DOC-BUCKET-EXAMPLE/alice/`, she will again receive an Access Denied error.

This pattern scales to a high number of users and buckets and simplifies management of those permissions. Rather than editing potentially large S3 bucket policies every time you want to add or remove an individual user-prefix access relationship, you can add and remove individual, discrete grants.

S3 Access Grants and corporate directory identities

You can use Amazon S3 Access Grants to grant access to AWS Identity and Access Management (IAM) principals (users or roles), both in the same AWS account and in others. However, in many cases, the entity accessing the data is an end user from your corporate directory. Instead of granting access to IAM principals, you can use S3 Access Grants to grant access directly to your corporate users and groups. With S3 Access Grants, you no longer need to map your corporate identities to intermediate IAM principals in order to access your S3 data through your corporate applications.

This new functionality—support for using end-user identities access to data—is provided by associating your S3 Access Grants instance with an AWS IAM Identity Center instance. IAM Identity Center supports standards-based identity providers and is the hub in AWS for any services or features, including S3 Access Grants, that support end-user identities. IAM Identity Center provides

authentication support for corporate identities through its trusted identity propagation feature. For more information, see [Trusted identity propagation across applications](#).

To get started with workforce identity support in S3 Access Grants, as a prerequisite, you start in IAM Identity Center by configuring identity provisioning between your corporate identity provider and IAM Identity Center. IAM Identity Center supports corporate identity providers such as Okta, Microsoft Entra ID (formerly Azure Active Directory), or any other external identity provider (IdP) that supports the System for Cross-domain Identity Management (SCIM) protocol. When you connect IAM Identity Center to your IdP and enable automatic provisioning, the users and groups from your IdP are synchronized into the identity store in IAM Identity Center. After this step, IAM Identity Center has its own view of your users and groups, so that you can refer to them by using other AWS services and features, such as S3 Access Grants. For more information about configuring IAM Identity Center automatic provisioning, see [Automatic provisioning in the AWS IAM Identity Center User Guide](#).

IAM Identity Center is integrated with AWS Organizations so that you can centrally manage permissions across multiple AWS accounts without configuring each of your accounts manually. In a typical organization, your identity administrator configures one IAM Identity Center instance for the entire organization, as a single point of identity synchronization. This IAM Identity Center instance typically runs in a dedicated AWS account in your organization. In this common configuration, you can refer to user and group identities in S3 Access Grants from any AWS account in the organization.

However, if your AWS Organizations administrator hasn't yet configured a central IAM Identity Center instance, you can create a local one in the same account as your S3 Access Grants instance. Such a configuration is more common for proof-of-concept or local development use cases. In all cases, the IAM Identity Center instance must be in the same AWS Region as the S3 Access Grants instance to which it will be associated.

In the following diagram of an IAM Identity Center configuration with an external IdP, the IdP is configured with SCIM to synchronize the identity store from the IdP to the identity store in IAM Identity Center.

To use your corporate directory identities with S3 Access Grants, do the following:

- Set up [Automatic provisioning](#) in IAM Identity Center to synchronize user and group information from your IdP into IAM Identity Center.
- Configure your external identity source within IAM Identity Center as a trusted token issuer. For more information, see [Trusted identity propagation across applications](#) in the *AWS IAM Identity Center User Guide*.
- Associate your S3 Access Grants instance with your IAM Identity Center instance. You can do this when you [create your S3 Access Grants instance](#). If you've already created your S3 Access Grants instance, see [Associate or disassociate your IAM Identity Center instance](#).

How directory identities can access S3 data

Suppose that you have corporate directory users who need to access your S3 data through a corporate application, for example, a document-viewer application, that is integrated with your external IdP (for example, Okta) to authenticate users. Authentication of the user in these applications is typically done through redirects in the user's web browser. Because users in the directory are not IAM principals, your application needs IAM credentials with which it can call the S3 Access Grants `GetDataAccess` API operation to [get access credentials to S3 data](#) on the users' behalf. Unlike IAM users and roles who get credentials themselves, your application needs a way to represent a directory user, who isn't mapped to an IAM role, so that the user can get data access through S3 Access Grants.

This transition, from authenticated directory user to an IAM caller that can make requests to S3 Access Grants on behalf of the directory user, is done by the application through the trusted token issuer feature of IAM Identity Center. The application, after authenticating the directory user, has an identity token from the IdP (for example, Okta) that represents the directory user according to Okta. The trusted token issuer configuration in IAM Identity Center enables the application to exchange this Okta token (the Okta tenant is configured as the "trusted issuer") for a different identity token from IAM Identity Center that will securely represent the directory user within AWS services. The data application will then assume an IAM role, providing the directory user's token from IAM Identity Center as additional context. The application can use the resulting IAM session to call S3 Access Grants. The token represents both the identity of the application (the IAM principal itself) as well as the directory user's identity.

The main step of this transition is the token exchange. The application performs this token exchange by calling the `CreateTokenWithIAM` API operation in IAM Identity Center. Of course, that too is an AWS API call and requires an IAM principal to sign it. The IAM principal that makes this request is typically an IAM role that's associated with the application. For example, if the application runs on Amazon EC2, the `CreateTokenWithIAM` request is typically performed by the IAM role that's associated with the EC2 instance on which the application runs. The result of a successful `CreateTokenWithIAM` call is a new identity token, which will be recognized within AWS services.

The next step, before the application can call `GetDataAccess` on the directory user's behalf, is for the application to obtain an IAM session that includes the directory user's identity. The application does this with an AWS Security Token Service (AWS STS) `AssumeRole` request that also includes the IAM Identity Center token for the directory user as additional identity context. This additional context is what enables IAM Identity Center to propagate the directory user's identity to the next step. The IAM role that the application assumes is the role that will need IAM permissions to call the `GetDataAccess` operation.

Having assumed the identity bearer IAM role with the IAM Identity Center token for the directory user as additional context, the application now has everything it needs to make a signed request to `GetDataAccess` on behalf of the authenticated directory user.

Token propagation is based on the following steps:

Create an IAM Identity Center application

First, create a new application in IAM Identity Center. This application will use a template that allows IAM Identity Center to identify which type of application settings that you can use. The

command to create the application requires you to provide the IAM Identity Center instance Amazon Resource Name (ARN), an application name, and the application provider ARN. The application provider is the SAML or OAuth application provider that the application will use to make calls to IAM Identity Center.

To use the following example command, replace the *user input placeholders* with your own information:

```
aws sso-admin create-application \
--instance-arn "arn:aws:sso::::instance/ssoins-ssoins-1234567890abcdef" \
--application-provider-arn "arn:aws:sso::::aws:applicationProvider/custom" \
--name MyDataApplication
```

Response:

```
{  
    "ApplicationArn": "arn:aws:sso:::123456789012:application/ssoins-  
    ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"  
}
```

Create a trusted token issuer

Now that you have your IAM Identity Center application, the next step is to configure a trusted token issuer that will be used to exchange your IdToken values from your IdP with IAM Identity Center tokens. In this step you need to provide the following items:

- The identity provider issuer URL
- The trusted token issuer name
- The claim attribute path
- The identity store attribute path
- The JSON Web Key Set (JWKS) retrieval option

The claim attribute path is the identity provider attribute that will be used to map to the identity store attribute. Normally, the claim attribute path is the email address of the user, but you can use other attributes to perform the mapping.

Create a file called `oidc-configuration.json` with the following information. To use this file, replace the *user input placeholders* with your own information.

```
{  
    "OidcJwtConfiguration":  
    {  
        "IssuerUrl": "https://login.microsoftonline.com/a1b2c3d4-abcd-1234-b7d5-  
b154440ac123/v2.0",  
        "ClaimAttributePath": "preferred_username",  
        "IdentityStoreAttributePath": "userName",  
        "JwksRetrievalOption": "OPEN_ID_DISCOVERY"  
    }  
}
```

To create the trusted token issuer, run the following command. To use this example command, replace the *user input placeholders* with your own information.

```
aws sso-admin create-trusted-token-issuer \  
--instance-arn "arn:aws:sso::::instance/ssoins-1234567890abcdef" \  
--name MyEntraIDTrustedIssuer \  
--trusted-token-issuer-type OIDC_JWT \  
--trusted-token-issuer-configuration file://./oidc-configuration.json
```

Response

```
{  
    "TrustedTokenIssuerArn": "arn:aws:sso:::123456789012:trustedTokenIssuer/  
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-a1b2c3d41234"  
}
```

Connect the IAM Identity Center application with the trusted token issuer

The trusted token issuer requires a few more configuration settings to work. Set the audience that the trusted token issuer will trust. The audience is the value inside the IdToken that's identified by the key and can be found in the identity provider settings. For example:

```
1234973b-abcd-1234-abcd-345c5a9c1234
```

Create a file named grant.json that contains the following content. To use this file, change the audience to match your identity provider settings and provide the trusted token issuer ARN that was returned by the previous command.

```
{
```

```
"JwtBearer":  
{  
    "AuthorizedTokenIssuers":  
    [  
        {  
            "TrustedTokenIssuerArn": "arn:aws:sso::123456789012:trustedTokenIssuer/  
ssoins-1234567890abcdef/tti-43b4a822-1234-1234-a1b2c3d41234",  
            "AuthorizedAudiences":  
            [  
                "1234973b-abcd-1234-abcd-345c5a9c1234"  
            ]  
        }  
    ]  
}
```

Run the following example command. To use this command, replace the *user input placeholders* with your own information.

```
aws sso-admin put-application-grant \  
--application-arn "arn:aws:sso::123456789012:application/ssoins-  
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \  
--grant-type "urn:ietf:params:oauth:grant-type:jwt-bearer" \  
--grant file://./grant.json \  

```

This command sets the trusted token issuer with configuration settings to trust the audience in the grant.json file and link this audience with the application created in the first step for exchanging tokens of the type jwt-bearer. The string `urn:ietf:params:oauth:grant-type:jwt-bearer` is not an arbitrary string. It is a registered namespace in OAuth JSON Web Token (JWT) assertion profiles. You can find more information about this namespace in [RFC 7523](#).

Next, use the following command to set up which scopes the trusted token issuer will include when exchanging IdToken values from your identity provider. For S3 Access Grants, the value for the --scope parameter is `s3:access_grants:read_write`.

```
aws sso-admin put-application-access-scope \  
--application-arn "arn:aws:sso::111122223333:application/ssoins-  
ssoins-111122223333abcdef/apl-abcd1234a1b2c3d" \  
--scope "s3:access_grants:read_write" \  

```

The last step is to attach a resource policy to the IAM Identity Center application. This policy will allow your application IAM role to make requests to the API operation `sso-oauth:CreateTokenWithIAM` and receive the `IdToken` values from IAM Identity Center.

Create a file named `authentication-method.json` that contains the following content. Replace `123456789012` with your account ID.

```
{  
    "Iam":  
        {  
            "ActorPolicy":  
                {  
                    "Version": "2012-10-17",  
                    "Statement":  
                        [  
                            {  
                                "Effect": "Allow",  
                                "Principal":  
                                    {  
                                        "AWS": "arn:aws:iam::123456789012:role/webapp"  
                                    },  
                                "Action": "sso-oauth:CreateTokenWithIAM",  
                                "Resource": "*"  
                            }  
                        ]  
                }  
        }  
}
```

To attach the policy to the IAM Identity Center application, run the following command:

```
aws sso-admin put-application-authentication-method \  
    --application-arn "arn:aws:sso::123456789012:application/ssoins-  
    ssoins-1234567890abcdef/apl-abcd1234a1b2c3d" \  
    --authentication-method-type IAM \  
    --authentication-method file://./authentication-method.json
```

This completes the configuration settings for using S3 Access Grants with directory users through a web application. You can test this setup directly in the application or you can call the `CreateTokenWithIAM` API operation by using the following command from an allowed IAM role in the IAM Identity Center application policy:

```
aws sso-oidc create-token-with-iam \
--client-id "arn:aws:sso::123456789012:application/ssoins-ssoins-1234567890abcdef/" \
apl-abcd1234a1b2c3d" \
--grant-type urn:ietf:params:oauth:grant-type:jwt-bearer \
--assertion IdToken
```

The response will be similar to this:

```
{  
    "accessToken": "<suppressed long string to reduce space>",  
    "tokenType": "Bearer",  
    "expiresIn": 3600,  
    "refreshToken": "<suppressed long string to reduce space>",  
    "idToken": "<suppressed long string to reduce space>",  
    "issuedTokenType": "urn:ietf:params:oauth:token-type:refresh_token",  
    "scope": [  
        "sts:identity_context",  
        "s3:access_grants:read_write",  
        "openid",  
        "aws"  
    ]  
}
```

If you decode the IdToken value that is encoded with base64, you can see the key-value pairs in JSON format. The key `sts:identity_context` contains the value that your application needs to send in the `sts:AssumeRole` request to include the identity information of the directory user. Here is an example of the IdToken decoded:

```
{  
    "aws:identity_store_id": "d-996773e796",  
    "sts:identity_context": "AQoJb3JpZ2luX2VjE0Tt1;<SUPPRESSED>",  
    "sub": "83d43802-00b1-7054-db02-f1d683aacba5",  
    "aws:instance_account": "123456789012",  
    "iss": "https://identitycenter.amazonaws.com/ssoins-1234567890abcdef",  
    "sts:audit_context": "AQoJb3JpZ2luX2VjE0T<SUPPRESSED>==",  
    "aws:identity_store_arn": "arn:aws:identitystore::232642235904:identitystore/  
d-996773e796",  
    "aud": "abcd12344U0gi7n4Yyp0-WV1LWNlbnRyYWwtMQ",  
    "aws:instance_arn": "arn:aws:sso:::instance/ssoins-6987d7fb04cf7a51",  
    "aws:credential_id": "EXAMPLEHI5glPh40y9TpApJn8...",  
    "act": {
```

```
    "sub": "arn:aws:sso::232642235904:trustedTokenIssuer/  
ssoins-6987d7fb04cf7a51/43b4a822-1020-7053-3631-cb2d3e28d10e"  
,  
    "auth_time": "2023-11-01T20:24:28Z",  
    "exp": 1698873868,  
    "iat": 1698870268  
}
```

You can get the value from `sts:identity_context` and pass this information in an `sts:AssumeRole` call. The following is a CLI example of the syntax. The role to be assumed is a temporary role with permissions to invoke `s3:GetDataAccess`.

```
aws sts assume-role \  
--role-arn "arn:aws:iam::123456789012:role/temp-role" \  
--role-session-name "TempDirectoryUserRole" \  
--provided-contexts ProviderArn="arn:aws:iam::aws:contextProvider/  
IdentityCenter",ContextAssertion="value from sts:identity_context"
```

You can now use the credentials received from this call to invoke the `s3:GetDataAccess` API operation and receive the final credentials with access to your S3 resources.

Getting started with S3 Access Grants

Amazon S3 Access Grants is an Amazon S3 feature that provides a scalable access control solution for your S3 data. S3 Access Grants is an S3 credential vendor, meaning that you register with S3 Access Grants your list of grants and at what level. Thereafter, when users or clients need access to your S3 data, they first ask S3 Access Grants for credentials. If there is a corresponding grant that authorizes access, S3 Access Grants vends temporary, least-privilege access credentials. The users or clients can then use S3 Access Grants vended credentials to access your S3 data. With that in mind, if your S3 data requirements mandate a complex or large permission configuration, you can use S3 Access Grants to scale S3 data permissions for users, groups, roles, and applications.

For most use cases, you can manage access control for your S3 data by using AWS Identity and Access Management (IAM) with bucket policies or IAM identity-based policies.

However, if you have complex S3 access control requirements, such as the following, you could benefit greatly from using S3 Access Grants:

- You are running into the bucket policy size limit of 20 KB.

- You grant human identities, for example, Microsoft Entra ID (formerly Azure Active Directory), Okta, or Ping users and groups, access to S3 data for analytics and big data.
- You must provide cross-account access without making frequent updates to IAM policies.
- Your data is unstructured and object-level rather than structured, in row and column format.

The S3 Access Grants workflow is as follows:

Steps	Description
1	<p>Create an S3 Access Grants instance</p> <p>To get started, initiate an S3 Access Grants instance that will contain your individual access grants.</p>
2	<p>Register a location</p> <p>Second, register an S3 data location (such as the default, s3://) and then specify a default IAM role that S3 Access Grants assumes when providing access to the S3 data location. You can also add custom locations to specific buckets or prefixes and map those to custom IAM roles.</p>
3	<p>Create grants</p> <p>Create individual permission grants. Specify in these permission grants the registered S3 location, the scope of data access within the location, the identity of the grantee, and their access level (READ, WRITE, or READWRITE).</p>
4	<p>Request access to S3 data</p> <p>When users, applications, and AWS services want to access S3 data, they first make an access request. S3 Access Grants determines if the request should be authorized. If there is a corresponding grant that authorizes access, S3 Access Grants uses the registered location's IAM role that's associated with that grant to vend temporary credentials back to the requester.</p>

Steps	Description
5	<p>Access S3 data</p> <p>Applications use the temporary credentials vended by S3 Access Grants to access S3 data.</p>

Working with S3 Access Grants instances

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

Topics

- [Create an S3 Access Grants instance](#)
- [Get the details of an S3 Access Grants instance](#)
- [List your S3 Access Grants instances](#)
- [Associate or disassociate your IAM Identity Center instance](#)
- [Delete an S3 Access Grants instance](#)

Create an S3 Access Grants instance

To get started with using AmazonS3 Access Grants, you first create an S3 Access Grants instance. You can create only one S3 Access Grants instance per AWS Region per account. The S3 Access Grants instance serves as the container for your S3 Access Grants resources, which include registered locations and grants.

With S3 Access Grants, you can create permission grants to your S3 data for AWS Identity and Access Management (IAM) users and roles. If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance. After you've done so, you can create access grants for your corporate users and groups. If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

You can create an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must first create an S3 Access Grants instance in the same AWS Region as your S3 data.

Prerequisites

If you want to grant access to your S3 data by using identities from your corporate directory, [add your corporate identity directory](#) to AWS IAM Identity Center. If you're not yet ready to do so, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

To create an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Access Grants**.
4. On the **S3 Access Grants** page, choose **Create S3 Access Grants instance**.
 - a. In **Step 1 of the Set up Access Grants instance wizard**, verify that you want to create the instance in the current AWS Region. Make sure that this is the same AWS Region where your S3 data is located. You can create one S3 Access Grants instance per AWS Region per account.
 - b. (Optional) If you've [added your corporate identity directory](#) to AWS IAM Identity Center, you can associate this IAM Identity Center instance of your corporate directory with your S3 Access Grants instance.

To do so, select **Add IAM Identity Center instance in *region***. Then enter the IAM Identity Center instance Amazon Resource Name (ARN).

If you haven't yet added your corporate directory to IAM Identity Center, you can associate your S3 Access Grants instance with an IAM Identity Center instance later.

- c. To create the S3 Access Grants instance, choose **Next**. To register a location, see [Step 2 - register a location](#).
5. If **Next or Create S3 Access Grants instance** is disabled:

Cannot create instance

- You might already have an S3 Access Grants instance in the same AWS Region. In the left navigation pane, choose **Access Grants**. On the **S3 Access Grants** page, scroll down to the **S3 Access Grants instance in your account** section to determine if an instance already exists.
- You might not have the `s3:CreateAccessGrantsInstance` permission which is required to create an S3 Access Grants instance. Contact your account administrator. For additional permissions that are required if you are associating an IAM Identity Center instance, with your S3 Access Grants instance, see [CreateAccessGrantsInstance](#) .

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example Create an S3 Access Grants instance

```
aws s3control create-access-grants-instance \
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{  
  "CreatedAt": "2023-05-31T17:54:07.893000+00:00",  
  "AccessGrantsInstanceId": "default",  
  "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
  default"
```

{}

Using the REST API

You can use the Amazon S3 REST API to create an S3 Access Grants instance. For information on the REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [AssociateAccessGrantsIdentityCenter](#)
- [CreateAccessGrantsInstance](#)
- [DeleteAccessGrantsInstance](#)
- [DissociateAccessGrantsIdentityCenter](#)
- [GetAccessGrantsInstance](#)
- [GetAccessGrantsInstanceForPrefix](#)
- [GetAccessGrantsInstanceResourcePolicy](#)
- [ListAccessGrantsInstances](#)
- [PutAccessGrantsInstanceResourcePolicy](#)

Using the AWS SDKs

This section provides an example of how to create an S3 Access Grants instance by using the AWS SDKs.

Java

This example creates the S3 Access Grants instance, which serves as a container for your individual access grants. You can have one S3 Access Grants instance per AWS Region in your account. The response includes the instance ID default and an Amazon Resource Name (ARN) that's generated for your S3 Access Grants instance.

Example Create an S3 Access Grants instance request

```
public void createAccessGrantsInstance() {  
    CreateAccessGrantsInstanceRequest createRequest =  
        CreateAccessGrantsInstanceRequest.builder().accountId("11122223333").build();  
    CreateAccessGrantsInstanceResponse createResponse =  
        s3Control.createAccessGrantsInstance(createRequest);  
    LOGGER.info("CreateAccessGrantsInstance  
" + createResponse);  
}
```

```
}
```

Response:

```
CreateAccessGrantsInstanceResponse(  
    CreatedAt=2023-06-07T01:46:20.507Z,  
    AccessGrantsInstanceId=default,  
    AccessGrantsInstanceArn=arn:aws:s3:us-east-2:111122223333:access-grants/default)
```

Get the details of an S3 Access Grants instance

You can get the details of your Amazon S3 Access Grants instance in a particular AWS Region. You can get the details of your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To get the details of an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the details of an S3 Access Grants instance

```
aws s3control get-access-grants-instance \  
--account-id 111122223333 \  
\\
```

```
--region us-east-2
```

Response:

```
{  
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/  
    default",  
    "AccessGrantsInstanceId": "default",  
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"  
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrantsInstance](#)
- [GetAccessGrantsInstanceForPrefix](#)

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get an S3 Access Grants instance

```
public void getAccessGrantsInstance() {  
    GetAccessGrantsInstanceRequest getRequest = GetAccessGrantsInstanceRequest.builder()  
        .accountId("111122223333")  
        .build();  
    GetAccessGrantsInstanceResponse getResponse =  
        s3Control.getAccessGrantsInstance(getRequest);  
    LOGGER.info("GetAccessGrantsInstanceResponse: " + getResponse);  
}
```

Response:

```
GetAccessGrantsInstanceResponse(  
AccessGrantsInstanceArn=arn:aws:s3:us-east-2: 111122223333:access-grants/default,  
CreatedAt=2023-06-07T01:46:20.507Z)
```

List your S3 Access Grants instances

You can list your S3 Access Grants instances, including the instances that have been shared with you through AWS Resource Access Manager (AWS RAM).

You can list your S3 Access Grants instances by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To list your S3 Access Grants instances

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. The **S3 Access Grants** page lists your S3 Access Grants instances and any cross-account instances that have been shared with your account. To view the details of an instance, choose **View details**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per AWS Region. This action also lists other cross-account S3 Access Grants instances that your account has access to.

```
aws s3control list-access-grants-instances \
```

```
--account-id 111122223333 \
--region us-east-2
```

Response:

```
{
    "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/default",
    "AccessGrantsInstanceId": "default",
    "CreatedAt": "2023-05-31T17:54:07.893000+00:00"
}
```

Using the REST API

For information about the Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [ListAccessGrantsInstances](#)

Using the AWS SDKs

This section provides examples of how to get the details of an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – List all S3 Access Grants instances for an account

This action lists the S3 Access Grants instances for an account. You can only have one S3 Access Grants instance per Region. This action can also list other cross-account S3 Access Grants instances that your account has access to.

```
public void listAccessGrantsInstances() {
    ListAccessGrantsInstancesRequest listRequest =
        ListAccessGrantsInstancesRequest.builder()
            .accountId("111122223333")
            .build();
    ListAccessGrantsInstancesResponse listResponse =
        s3Control.listAccessGrantsInstances(listRequest);
```

```
LOGGER.info("ListAccessGrantsInstancesResponse: " + listResponse);  
}
```

Response:

```
ListAccessGrantsInstancesResponse(  
AccessGrantsInstancesList=[  
ListAccessGrantsInstanceEntry(  
AccessGrantsInstanceId=default,  
AccessGrantsInstanceArn=arn:aws:s3:us-east-2:1112222333:access-grants/default,  
CreatedAt=2023-06-07T04:28:11.728Z  
)  
]  
)
```

Associate or disassociate your IAM Identity Center instance

In Amazon S3 Access Grants, you can associate the AWS IAM Identity Center instance of your corporate identity directory with an S3 Access Grants instance. After you do so, you can create access grants for your corporate directory users and groups, in addition to AWS Identity and Access Management (IAM) users and roles.

If you no longer want to create access grants for your corporate directory users and groups, you can disassociate your IAM Identity Center instance from your S3 Access Grants instance.

You can associate or disassociate an IAM Identity Center instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

Before you associate your IAM Identity Center instance with your S3 Access Grants instance, you must add your corporate identity directory to IAM Identity Center. For more information, see [the section called “S3 Access Grants and corporate directory identities”](#).

To associate an IAM Identity Center instance with an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.

3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, in the **IAM Identity Center** section, choose to either **Add** an IAM Identity Center instance or **Deregister** an already associated IAM Identity Center instance.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Associate an IAM Identity Center instance with an S3 Access Grants instance

```
aws s3control associate-access-grants-identity-center \
--account-id 111122223333 \
--identity-center-arn arn:aws:sso::::instance/ssoins-1234a567bb89012c \
--profile access-grants-profile \
--region eu-central-1

// No response body
```

Example – Disassociate an IAM Identity Center instance from an S3 Access Grants instance

```
aws s3control dissociate-access-grants-identity-center \
--account-id 111122223333 \
--profile access-grants-profile \
--region eu-central-1

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing the association between an IAM Identity Center instance and an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [AssociateAccessGrantsIdentityCenter](#)
- [DissociateAccessGrantsIdentityCenter](#)

Delete an S3 Access Grants instance

You can delete an Amazon S3 Access Grants instance from an AWS Region in your account.

However, before you can delete an S3 Access Grants instance, you must first do the following:

- Delete all resources within the S3 Access Grants instance, including all grants and locations. For more information, see [Delete a grant](#) and [Delete a location](#).
- If you've associated an AWS IAM Identity Center instance with your S3 Access Grants instance, you must disassociate the IAM Identity Center instance. For more information, see [Associate or disassociate your IAM Identity Center instance](#).

Important

If you delete an S3 Access Grants instance, the deletion is permanent and can't be undone.

All grantees that were given access through the grants in this S3 Access Grants instance will lose access to your S3 data.

You can delete an S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the instance details page, choose **Delete instance** in the upper-right corner.
6. In the dialog box that appears, choose **Delete**. This action can't be undone.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Note

Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example – Delete an S3 Access Grants instance

```
aws s3control delete-access-grants-instance \
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--endpoint-url https://s3-control.us-east-2.amazonaws.com \

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting an S3 Access Grants instance, see [DeleteAccessGrantsInstance](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an S3 Access Grants instance by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Note

Before you can delete an S3 Access Grants instance, you must first delete all grants and locations created within the S3 Access Grants instance. If you have associated an

IAM Identity Center center instance with your S3 Access Grants instance, you must disassociate it first.

Example – Delete an S3 Access Grants instance

```
public void deleteAccessGrantsInstance() {  
    DeleteAccessGrantsInstanceRequest deleteRequest =  
        DeleteAccessGrantsInstanceRequest.builder()  
            .accountId("111122223333")  
            .build();  
    DeleteAccessGrantsInstanceResponse deleteResponse =  
        s3Control.deleteAccessGrantsInstance(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsInstanceResponse: " + deleteResponse);  
}
```

Working with S3 Access Grants locations

After you [create an Amazon S3 Access Grants instance](#) in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

You can register a location, view a location's details, edit a location, and delete a location.

Note

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see [Create grants](#).

Topics

- [Register a location](#)
- [View the details of a registered location](#)

- [Update a registered location](#)
- [Delete a registered location](#)

Register a location

After you [create an Amazon S3 Access Grants instance](#) in an AWS Region in your account, you register an S3 location in that instance. An S3 Access Grants location maps the default S3 location (`s3://`), a bucket, or a prefix to an AWS Identity and Access Management (IAM) role. S3 Access Grants assumes this IAM role to vend temporary credentials to the grantee that is accessing that particular location. You must first register at least one location in your S3 Access Grants instance before you can create an access grant.

Recommended use case

We recommend that you register the default location (`s3://`) and map it to an IAM role. The location at the default S3 path (`s3://`) covers access to all of your S3 buckets in that AWS Region of your account. When you create an access grant, you can narrow the grant scope to a bucket, a prefix, or an object within the default location.

Complex access-management use cases

More complex access-management use cases might require you to register more than the default location. Some examples of such use cases are:

- Suppose that the `amzn-s3-demo-bucket` is a registered location in your S3 Access Grants instance with an IAM role mapped to it, but this IAM role is denied access to a particular prefix within the bucket. In this case, you can register the prefix that the IAM role does not have access to as a separate location and map that location to a different IAM role with the necessary access.
- Suppose that you want to create grants that restrict access to only the users within a virtual private cloud (VPC) endpoint. In this case, you can register a location for a bucket in which the IAM role restricts access to the VPC endpoint. Later, when a grantee asks S3 Access Grants for credentials, S3 Access Grants assumes the location's IAM role to vend the temporary credentials. This credential will deny access to the specific bucket unless the caller is within the VPC endpoint. This deny permission is applied in addition to the regular READ, WRITE, or READWRITE permission specified in the grant.

When you register a location, you must also specify the IAM role that S3 Access Grants assumes to vend temporary credentials and to scope the permissions for a specific grant.

If your use case requires you to register multiple locations in your S3 Access Grants instance, you can register any of the following:

S3 URI	IAM role	Description
s3://	<i>Default-IAM-role</i>	The default location, s3://, includes all buckets in the AWS Region.
s3:// <i>amzn-s3-demo-bucket1</i> /	<i>IAM-role-For-bucket</i>	This location includes all objects in the specified bucket.
s3:// <i>amzn-s3-demo-bucket1</i> / <i>prefix-name</i>	<i>IAM-role-For-prefix</i>	This location includes all objects in the bucket with an object key name that starts with this prefix.

Before you can register a specific bucket or prefix, make sure that you do the following:

- Create one or more buckets that contain the data that you want to grant access to. These buckets must be located in the same AWS Region as your S3 Access Grants instance. For more information, see [Creating a bucket](#).

Adding a prefix is an optional step. Prefixes are strings at the beginning of an object key name. You can use them to organize objects in your bucket as well as for access management. To add a prefix to a bucket, see [Creating object key names](#).

- Create an IAM role that has permission to access your S3 data in the AWS Region. For more information, see [Creating IAM roles](#) in the *AWS IAM Identity Center user guide*.
- In the IAM role trust policy, give the S3 Access Grants service (`access-grants.s3.amazonaws.com`) principal access to the IAM role that you created. To do so, you can create a JSON file that contains the following statements. To add the trust policy to your account, see [Create a role using custom trust policies](#).

TestRolePolicy.json

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1234567891011",
```

```
"Effect": "Allow",
"Principal": {
    "Service": "access-grants.s3.amazonaws.com"
},
>Action": [
    "sts:AssumeRole",
    "sts:SetSourceIdentity"
],
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "accountId",
        "aws:SourceArn": "arn:aws:s3:region:accountId:access-grants/default"
    }
}
},
// Optionally, for an IAM Identity Center use case, add:
{
    "Sid": "Stmt1234567891012",
    "Effect": "Allow",
    "Principal": {
        "Service": "access-grants.s3.amazonaws.com"
    },
    "Action": "sts:SetContext",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "accountId",
            "aws:SourceArn": "arn:aws:s3:region:accountId:access-grants/default"
        },
        "ForAllValues:ArnEquals": {
            "sts:RequestContextProviders": "arn:aws:iam::aws:contextProvider/
IdentityCenter"
        }
    }
}
]
```

- Create an IAM policy to attach Amazon S3 permissions to the IAM role that you created. See the following example `iam-policy.json` file and replace the *user input placeholders* with your own information.

Note

- If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example includes the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.
- You can restrict the IAM role to access S3 data only if the credentials are vended by S3 Access Grants. This example shows you how to add a Condition statement for a specific S3 Access Grants instance. To use this Condition, replace the S3 Access Grants instance ARN in the Condition statement with your S3 Access Grants instance ARN, which has the format: `arn:aws:s3:region:accountId:access-grants/default`

iam-policy.json

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ObjectLevelReadPermissions",  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion",  
                "s3:GetObjectAcl",  
                "s3:GetObjectVersionAcl",  
                "s3>ListMultipartUploadParts"  
            ],  
            "Resource": [  
                "arn:aws:s3:::*"  
            ],  
            "Condition": {  
                "StringEquals": { "aws:ResourceAccount": "accountId" },  
                "ArnEquals": {  
                    "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-  
grants/default"]  
                }  
            }  
        }  
    ]  
}
```

```
},
{
    "Sid": "ObjectLevelWritePermissions",
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:PutObjectVersionAcl",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion",
        "s3:AbortMultipartUpload"
    ],
    "Resource": [
        "arn:aws:s3:::*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "accountId" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
Region:accountId:access-grants/default"]
        }
    }
},
{
    "Sid": "BucketLevelReadPermissions",
    "Effect": "Allow",
    "Action": [
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "accountId" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS
Region:accountId:access-grants/default"]
        }
    }
},
//Optionally add the following section if you use SSE-KMS encryption
{
    "Sid": "KMSPermissions",
    "Effect": "Allow",
```

```
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "*"
    ]
}
]
```

You can register a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

Note

After you register the first location in your S3 Access Grants instance, your instance still does not have any individual access grants in it. To create an access grant, see [Create grants](#).

Using the S3 console

Before you can grant access to your S3 data with S3 Access Grants, you must have at least one registered location.

To register a location in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

If you're using S3 Access Grants instance for the first time, make sure that you have completed [Step 1 - create an S3 Access Grants instance](#) and navigated to [Step 2 of the Set up Access Grants instance wizard](#). If you already have an S3 Access Grants instance, choose **View details**, and then from the **Locations** tab, choose **Register location**.

- a. For the **Location scope**, choose **Browse S3** or enter the S3 URI path to the location that you want to register. For S3 URI formats, see the [location formats](#) table. After you enter a URI, you can choose **View** to browse the location.
- b. For the **IAM role**, choose one of the following:

- **Choose from existing IAM roles**

Choose an IAM role from the dropdown list. After you choose a role, choose **View** to make sure that this role has the necessary permissions to manage the location that you're registering. Specifically, make sure that this role grants S3 Access Grants the permissions `sts:AssumeRole` and `sts:SetSourceIdentity`.

- **Enter IAM role ARN**

Navigate to the [IAM Console](#). Copy the Amazon Resource Name (ARN) of the IAM role and paste it in this box.

- c. To finish, choose **Next or Register location**.

4. Troubleshooting:

Cannot register location

- The location might already be registered.

You might not have the `s3:CreateAccessGrantsLocation` permission to register locations. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *user input placeholders* with your own information.

Example Create a resource policy

Create a policy that allows S3 Access Grants to assume the IAM role. To do so, you can create a JSON file that contains the following statements. To add the resource policy to your account, see [Create and attach your first customer managed policy](#).

TestRolePolicy.json

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Stmt1234567891011",  
            "Action": ["sts:AssumeRole", "sts:SetSourceIdentity"],  
            "Effect": "Allow",  
            "Principal": {"Service": "access-grants.s3.amazonaws.com"}  
        }  
    ]  
}
```

Example Create the role

Run the following IAM command to create the role.

```
aws iam create-role --role-name accessGrantsTestRole \  
--region us-east-2 \  
--assume-role-policy-document file://TestRolePolicy.json
```

Running the `create-role` command returns the policy:

```
{  
    "Role": {  
        "Path": "/",  
        "RoleName": "accessGrantsTestRole",  
        "RoleId": "AROASRDGX4WM4GH55GIDA",  
        "Arn": "arn:aws:iam::111122223333:role/accessGrantsTestRole",  
        "CreateDate": "2023-05-31T18:11:06+00:00",  
        "AssumeRolePolicyDocument": {  
            "Version": "2012-10-17",  
            "Statement": [  
                {  
                    "Sid": "Stmt1685556427189",  
                    "Action": ["sts:AssumeRole", "sts:SetSourceIdentity"],  
                    "Effect": "Allow",  
                    "Principal": {"Service": "access-grants.s3.amazonaws.com"}  
                }  
            ]  
        }  
    }  
}
```

```
        "Action": [
            "sts:AssumeRole",
            "sts:SetSourceIdentity"
        ],
        "Effect": "Allow",
        "Principal": {
            "Service": "access-grants.s3.amazonaws.com"
        }
    }
]
```

Example

Create an IAM policy to attach Amazon S3 permissions to the IAM role. See the following example `iam-policy.json` file and replace the *user input placeholders* with your own information.

Note

If you use server-side encryption with AWS Key Management Service (AWS KMS) keys to encrypt your data, the following example adds the necessary AWS KMS permissions for the IAM role in the policy. If you do not use this feature, you can remove these permissions from your IAM policy.

To make sure that the IAM role can only be used to access data in S3 if the credentials are vended out by S3 Access Grants, this example shows you how to add a Condition statement that specifies the S3 Access Grants instance (`s3:AccessGrantsInstance: InstanceArn`) in your IAM policy. When using following example policy, replace the *user input placeholders* with your own information.

`iam-policy.json`

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ObjectLevelReadPermissions",
            "Effect": "Allow",
```

```
"Action": [
    "s3:GetObject",
    "s3:GetObjectVersion",
    "s3:GetObjectAcl",
    "s3:GetObjectVersionAcl",
    "s3>ListMultipartUploadParts"
],
"Resource": [
    "arn:aws:s3:::*"
],
"Condition": {
    "StringEquals": { "aws:ResourceAccount": "accountId" },
    "ArnEquals": {
        "s3:AccessGrantsInstanceArn": ["arn:aws:s3:region:accountId:access-
grants/default"]
    }
},
{
    "Sid": "ObjectLevelWritePermissions",
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:PutObjectVersionAcl",
        "s3>DeleteObject",
        "s3>DeleteObjectVersion",
        "s3:AbortMultipartUpload"
    ],
    "Resource": [
        "arn:aws:s3:::*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "accountId" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-
grants/default"]
        }
    }
},
{
    "Sid": "BucketLevelReadPermissions",
    "Effect": "Allow",
    "Action": [
```

```
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::/*"
    ],
    "Condition": {
        "StringEquals": { "aws:ResourceAccount": "accountId" },
        "ArnEquals": {
            "s3:AccessGrantsInstanceArn": ["arn:aws:s3:AWS Region:accountId:access-
grants/default"]
        }
    },
    {
        "Sid": "KMSPermissions",
        "Effect": "Allow",
        "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
        ],
        "Resource": [
            "*"
        ]
    }
]
```

Example

Run the following command:

```
aws iam put-role-policy \
--role-name accessGrantsTestRole \
--policy-name accessGrantsTestRole \
--policy-document file://iam-policy.json
```

Example Register the default location

```
aws s3control create-access-grants-location \
--account-id 111122223333 \
--location-scope s3:// \
--iam-role-arn arn:aws:iam::111122223333:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
 "AccessGrantsLocationId": "default",
 "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/
 default/location/default",
 "LocationScope": "s3://"
 "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Example Register a custom location

```
aws s3control create-access-grants-location \
--account-id 111122223333 \
--location-scope s3://DOC-BUCKET-EXAMPLE/ \
--iam-role-arn arn:aws:iam::123456789012:role/accessGrantsTestRole
```

Response:

```
{"CreatedAt": "2023-05-31T18:23:48.107000+00:00",
 "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",
 "AccessGrantsLocationArn": "arn:aws:s3:us-east-2: 111122223333:access-grants/
 default/location/635f1139-1af2-4e43-8131-a4de006eb888",
 "LocationScope": "s3://DOC-BUCKET-EXAMPLE/",
 "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"
}
```

Using the REST API

For information about Amazon S3 REST API support for managing an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [CreateAccessGrantsLocation](#)
- [DeleteAccessGrantsLocation](#)
- [GetAccessGrantsLocation](#)
- [ListAccessGrantsLocations](#)
- [UpdateAccessGrantsLocation](#)

Using the AWS SDKs

This section provides examples of how to register locations by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

You can register the default location, `s3://`, or a custom location in your S3 Access Grants instance. Make sure that you first create an IAM role with principal access to the location, and then make sure that you grant S3 Access Grants permission to assume this role.

To use the following example commands, replace the *user input placeholders* with your own information.

Example Register a default location

Request:

```
public void createAccessGrantsLocation() {  
    CreateAccessGrantsLocationRequest createRequest =  
        CreateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .locationScope("s3://")  
            .iamRoleArn("arn:aws:iam::123456789012:role/accessGrantsTestRole")  
            .build();  
    CreateAccessGrantsLocationResponse createResponse =  
        s3Control.createAccessGrantsLocation(createRequest);  
    LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);  
}
```

Response:

```
CreateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:11.027Z,  
    AccessGrantsLocationId=default,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
    location/default,  
    LocationScope=s3://,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole
```

)

Example Register a custom location

Request:

```
public void createAccessGrantsLocation() {  
    CreateAccessGrantsLocationRequest createRequest =  
        CreateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .locationScope("s3://DOC-BUCKET-EXAMPLE/")  
            .iamRoleArn("arn:aws:iam::111122223333:role/accessGrantsTestRole")  
            .build();  
    CreateAccessGrantsLocationResponse createResponse =  
        s3Control.createAccessGrantsLocation(createRequest);  
    LOGGER.info("CreateAccessGrantsLocationResponse: " + createResponse);  
}
```

Response:

```
CreateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:10.027Z,  
    AccessGrantsLocationId=18cfe6fb-eb5a-4ac5-aba9-8d79f04c2012,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
    location/18cfe6fb-eb5a-4ac5-aba9-8d79f04c2666,  
    LocationScope= s3://test-bucket-access-grants-user123/,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
)
```

View the details of a registered location

You can get the details of a location that's registered in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the locations registered in your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the registered location that you want to view. To filter the list of registered locations, use the search box.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the details of a registered location

```
aws s3control get-access-grants-location \  
--account-id 111122223333 \  
--access-grants-location-id default
```

Response:

```
{  
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
    "AccessGrantsLocationId": "default",  
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/default",  
    "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
}
```

Example – List all of the locations that are registered in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally use the `--location-scope` `s3://bucket-and-or-prefix` parameter.

```
aws s3control list-access-grants-locations \  
--account-id 111122223333 \  
--location-scope s3://my-bucket
```

```
--region us-east-2
```

Response:

```
{"AccessGrantsLocationsList": [  
    {  
        "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
        "AccessGrantsLocationId": "default",  
        "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/default",  
        "LocationScope": "s3://"  
        "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
    },  
    {  
        "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
        "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb456",  
        "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:111122223333:access-grants/  
default/location/635f1139-1af2-4e43-8131-a4de006eb888",  
        "LocationScope": "s3://amzn-s3-demo-bucket/prefixA*",  
        "IAMRoleArn": "arn:aws:iam::111122223333:role/accessGrantsTestRole"  
    }  
]
```

Using the REST API

For information about the Amazon S3 REST API support for getting the details of a registered location or listing all of the locations that are registered with an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrantsLocation](#)
- [ListAccessGrantsLocations](#)

Using the AWS SDKs

This section provides examples of how to get the details of a registered location or list all of the registered locations in an S3 Access Grants instance by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get the details of a registered location

```
public void getAccessGrantsLocation() {  
    GetAccessGrantsLocationRequest getAccessGrantsLocationRequest =  
        GetAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .accessGrantsLocationId("default")  
            .build();  
    GetAccessGrantsLocationResponse getAccessGrantsLocationResponse =  
        s3Control.getAccessGrantsLocation(getAccessGrantsLocationRequest);  
    LOGGER.info("GetAccessGrantsLocationResponse: " + getAccessGrantsLocationResponse);  
}
```

Response:

```
GetAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:10.027Z,  
    AccessGrantsLocationId=default,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
    location/default,  
    LocationScope= s3://,  
    IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
)
```

Example – List all registered locations in an S3 Access Grants instance

To restrict the results to an S3 prefix or bucket, you can optionally pass an S3 URI, such as `s3://bucket-and-or-prefix`, in the LocationScope parameter.

```
public void listAccessGrantsLocations() {  
  
    ListAccessGrantsLocationsRequest listRequest =  
        ListAccessGrantsLocationsRequest.builder()  
            .accountId("111122223333")  
            .build();  
  
    ListAccessGrantsLocationsResponse listResponse =  
        s3Control.listAccessGrantsLocations(listRequest);  
    LOGGER.info("ListAccessGrantsLocationsResponse: " + listResponse);  
}
```

Response:

```
ListAccessGrantsLocationsResponse(  
    AccessGrantsLocationsList=[  
        ListAccessGrantsLocationsEntry(  
            CreatedAt=2023-06-07T04:35:11.027Z,  
            AccessGrantsLocationId=default,  
            AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
                location/default,  
            LocationScope=s3://,  
            IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
        ),  
        ListAccessGrantsLocationsEntry(  
            CreatedAt=2023-06-07T04:35:10.027Z,  
            AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb456,  
            AccessGrantsLocationArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
                location/635f1139-1af2-4e43-8131-a4de006eb888,  
            LocationScope=s3://amzn-s3-demo-bucket/prefixA*,  
            IAMRoleArn=arn:aws:iam::111122223333:role/accessGrantsTestRole  
        )  
    ]  
)
```

Update a registered location

You can update the AWS Identity and Access Management (IAM) role of a location that's registered in your Amazon S3 Access Grants instance. For each new IAM role that you use to register a location in S3 Access Grants, be sure to give the S3 Access Grants service principal (`access-grants.s3.amazonaws.com`) access to this role. To do this, add an entry for the new IAM role in the same trust policy JSON file that you used when you first [registered the location](#).

You can update a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To update the IAM role of a location registered with your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.

3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the options button next to the registered location that you want to update.
8. Update the IAM role, and then choose **Save changes**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Update the IAM role of a registered location

```
aws s3control update-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id 635f1139-1af2-4e43-8131-a4de006eb999 \
--iam-role-arn arn:aws:iam::777788889999:role/accessGrantsTestRole
```

Response:

```
{  
    "CreatedAt": "2023-05-31T18:23:48.107000+00:00",  
    "AccessGrantsLocationId": "635f1139-1af2-4e43-8131-a4de006eb999",  
    "AccessGrantsLocationArn": "arn:aws:s3:us-east-2:777788889999:access-grants/  
default/location/635f1139-1af2-4e43-8131-a4de006eb888",  
    "LocationScope": "s3://amzn-s3-demo-bucket/prefixB*",  
    "IAMRoleArn": "arn:aws:iam::777788889999:role/accessGrantsTestRole"  
}
```

Using the REST API

For information on the Amazon S3 REST API support for updating a location in an S3 Access Grants instance, see [UpdateAccessGrantsLocation](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to update the IAM role of a registered location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Update the IAM role of a registered location

```
public void updateAccessGrantsLocation() {  
    UpdateAccessGrantsLocationRequest updateRequest =  
        UpdateAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .accessGrantsLocationId("635f1139-1af2-4e43-8131-a4de006eb999")  
            .iamRoleArn("arn:aws:iam::777788889999:role/accessGrantsTestRole")  
            .build();  
    UpdateAccessGrantsLocationResponse updateResponse =  
        s3Control.updateAccessGrantsLocation(updateRequest);  
    LOGGER.info("UpdateAccessGrantsLocationResponse: " + updateResponse);  
}
```

Response:

```
UpdateAccessGrantsLocationResponse(  
    CreatedAt=2023-06-07T04:35:10.027Z,  
    AccessGrantsLocationId=635f1139-1af2-4e43-8131-a4de006eb999,  
    AccessGrantsLocationArn=arn:aws:s3:us-east-2:777788889999:access-grants/default/  
    location/635f1139-1af2-4e43-8131-a4de006eb888,  
    LocationScope=s3://amzn-s3-demo-bucket/prefixB*,  
    IAMRoleArn=arn:aws:iam::777788889999:role/accessGrantsTestRole  
)
```

Delete a registered location

You can delete a location registration from an Amazon S3 Access Grants instance. Deleting the location deregisters it from the S3 Access Grants instance.

Before you can remove a location registration from an S3 Access Grants instance, you must delete all of the grants that are associated with this location. For information about how to delete grants, see [Delete a grant](#).

You can delete a location in your S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete a location registration from your S3 Access Grants instance

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page for the instance, choose the **Locations** tab.
6. Find the location that you want to update. To filter the list of locations, use the search box.
7. Choose the option button next to the registered location that you want to delete.
8. Choose **Deregister**.
9. A dialog box appears that warns you that this action can't be undone. To delete the location, choose **Deregister**.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Delete a location registration

```
aws s3control delete-access-grants-location \
--account-id 111122223333 \
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

```
// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for deleting a location from an S3 Access Grants instance, see [DeleteAccessGrantsLocation](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how to delete a location by using the AWS SDKs.

To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Delete a location registration

```
public void deleteAccessGrantsLocation() {  
    DeleteAccessGrantsLocationRequest deleteRequest =  
        DeleteAccessGrantsLocationRequest.builder()  
            .accountId("111122223333")  
            .accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLE1111")  
            .build();  
    DeleteAccessGrantsLocationResponse deleteResponse =  
        s3Control.deleteAccessGrantsLocation(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsLocationResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantsLocationResponse()
```

Working with grants in S3 Access Grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps

buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you [register at least one location](#) in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you [associated with your S3 Access Grants instance](#). For more information, see [S3 Access Grants and corporate directory identities](#). To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, a1b2c3d4-5678-90ab-cdef-EXAMPLE11111. For more information about how to use IAM Identity Center to view user information, see [View user and group assignments](#) in the *AWS IAM Identity Center user guide*.

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket. This can be any string of allowed characters, for example, object key names in your bucket that start with the engineering/ prefix.

Create grants

An individual access *grant* in an S3 Access Grants instance allows a specific identity—an AWS Identity and Access Management (IAM) principal, or a user or group in a corporate directory—to get access within a location that is registered in your S3 Access Grants instance. A location maps buckets or prefixes to an IAM role. S3 Access Grants assumes this IAM role to vend temporary credentials to grantees.

After you [register at least one location](#) in your S3 Access Grants instance, you can create an access grant.

The grantee can be an IAM user or role or a directory user or group. A directory user is a user from your corporate directory or external identity source that you [associated with your S3](#)

[Access Grants instance](#). For more information, see [S3 Access Grants and corporate directory identities](#). To create a grant for a specific directory user or group from IAM Identity Center, find the GUID that IAM Identity Center uses to identify that user in IAM Identity Center, for example, a1b2c3d4-5678-90ab-cdef-EXAMPLE11111. For more information about how to use IAM Identity Center to view user information, see [View user and group assignments in the AWS IAM Identity Center user guide](#).

You can grant access to a bucket, a prefix, or an object. A prefix in Amazon S3 is a string of characters in the beginning of an object key name that is used to organize objects within a bucket. This can be any string of allowed characters, for example, object key names in your bucket that start with the engineering/ prefix.

Subprefix

When granting access to a registered location, you can use the Subprefix field to narrow the scope of access to a subset of the location scope. If the registered location that you choose for the grant is the default S3 path (s3://), you must narrow the grant scope. You cannot create an access grant for the default location (s3://), which would give the grantee access to every bucket in an AWS Region. Instead, you must narrow the grant scope to one of the following:

- A bucket: s3://*bucket*/*
- A prefix within a bucket: s3://*bucket/prefix**
- A prefix within a prefix: s3://*bucket/prefixA/prefixB**
- An object: s3://*bucket/object-key-name*

If you are creating an access grant where the registered location is a bucket, you can pass one of the following in the Subprefix field to narrow the grant scope:

- A prefix within the bucket: *prefix**
- A prefix within a prefix: *prefixA/prefixB**
- An object: /*object-key-name*

After you create the grant, the grant scope that's displayed in the Amazon S3 console or the GrantScope that is returned in the API or AWS Command Line Interface (AWS CLI) response is the result of concatenating the location path with the Subprefix. Make sure that this concatenated path maps correctly to the S3 bucket, prefix, or object to which you want to grant access.

Note

- If you need to create an access grant that grants access to only one object, you must specify that the grant type is for an object. To do this in an API call or a CLI command, pass the `s3PrefixType` parameter with the value `Object`. In the Amazon S3 console, when you create the grant, after you select a location, under **Grant Scope**, select the **Grant scope is an object** checkbox.
- You cannot create a grant to a bucket if the bucket does not yet exist. However, you can create a grant to a prefix that does not yet exist.
- For the maximum number of grants that you can create in your S3 Access Grants instance, see [S3 Access Grants limitations](#).

You can create an access grant by using the Amazon S3 console, AWS CLI, the Amazon S3 REST API, and AWS SDKs.

Using the S3 console

To create an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.

If you're using the S3 Access Grants instance for the first time, make sure that you have completed [Step 2 - register a location](#) and navigated to [Step 3 of the Set up Access Grants instance wizard](#). If you already have an S3 Access Grants instance, choose **View details**, and then from the **Grants** tab, choose **Create grant**.

- a. In the **Grant scope** section, select or enter a registered location.

If you selected the default `s3://` location, use the **Subprefix** box to narrow the scope of the access grant. For more information, see [Subprefix](#). If you're granting access only to an object, select **Grant scope is an object**.

- b. Under **Permissions and access**, select the **Permission** level, either **Read**, **Write**, or both.

Then choose the **Grantee type**. If you have added your corporate directory to IAM Identity Center and associated this IAM Identity Center instance with your S3 Access Grants instance, you can choose **Directory identity from IAM Identity Center**. If you choose this option, get the ID of the user or group from IAM Identity Center and enter it in this section.

If the **Grantee type** is an IAM user or role, choose **IAM principal**. Under **IAM principal type**, choose **User or Role**. Then, under **IAM principal user**, either choose from the list or enter the identity's ID.

- c. To create the S3 Access Grants grant, choose **Next or Create grant**.
4. If **Next or Create grant** is disabled:

Cannot create grant

- You might need to [register a location](#) first in your S3 Access Grants instance.
- You might not have the s3:CreateAccessGrant permission to create an access grant. Contact your account administrator.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The following examples show how to create an access grant request for an IAM principal and how to create an access grant request for a corporate directory user or group.

To use the following example commands, replace the *user input placeholders* with your own information.

Note

If you're creating an access grant that grants access to only one object, include the required parameter --s3-prefix-type Object.

Example Create an access grant request for an IAM principal

```
aws s3control create-access-grant \
--account-id 111122223333 \
```

```
--access-grants-location-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 \
--access-grants-location-configuration S3SubPrefix=prefixB* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::123456789012:user/data-consumer-3
```

Example Create an access grant response

```
{"CreatedAt": "2023-05-31T18:41:34.663000+00:00",
  "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
  "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/grant/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
  "Grantee": {
    "GranteeType": "IAM",
    "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
  },
  "AccessGrantsLocationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
  "AccessGrantsLocationConfiguration": {
    "S3SubPrefix": "prefixB*"
  },
  "GrantScope": "s3://DOC-BUCKET-EXAMPLE/prefix*",
  "Permission": "READ"
}
```

Create an access grant request for a directory user or group

To create an access grant request for a directory user or group, you must first get the GUID for the directory user or group by running one of the following commands.

Example Get a GUID for a directory user or group

You can find the GUID of an IAM Identity Center user through the IAM Identity Center console or by using the AWS CLI or AWS SDKs. The following command lists the users in the specified IAM Identity Center instance, with their names and identifiers.

```
aws identitystore list-users --identity-store-id d-1a2b3c4d1234
```

This command lists the groups in the specified IAM Identity Center instance.

```
aws identitystore list-groups --identity-store-id d-1a2b3c4d1234
```

Example Create an access grant for a directory user or group

This command is similar to creating a grant for IAM users or roles, except the grantee type is DIRECTORY_USER or DIRECTORY_GROUP, and the grantee identifier is the GUID for the directory user or group.

```
aws s3control create-access-grant \
--account-id 123456789012 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix="amzn-s3-demo-bucket/rafael/*" \
--permission READWRITE \
--grantee GranteeType=DIRECTORY_USER,GranteeIdentifier=83d43802-00b1-7054-db02-
f1d683aacba5 \
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [CreateAccessGrant](#)
- [DeleteAccessGrant](#)
- [GetAccessGrant](#)
- [ListAccessGrants](#)

Using the AWS SDKs

This section provides examples of how to create an access grant by using the AWS SDKs.

Java

To use the following example, replace the *user input placeholders* with your own information:

 **Note**

If you are creating an access grant that grants access to only one object, include the required parameter .s3PrefixType(S3PrefixType.Object).

Example Create an access grant request

```
public void createAccessGrant() {  
    CreateAccessGrantRequest createRequest = CreateAccessGrantRequest.builder()  
        .accountId("111122223333")  
        .accessGrantsLocationId("a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaaa")  
        .permission("READ")  
        .accessGrantsLocationConfiguration(AccessGrantsLocationConfiguration.builder().s3SubPrefix(""  
        .grantee(Grantee.builder().granteeType("IAM").granteeIdentifier("arn:aws:iam::111122223333:u  
data-consumer-3").build())  
        .build();  
    CreateAccessGrantResponse createResponse =  
        s3Control.createAccessGrant(createRequest);  
    LOGGER.info("CreateAccessGrantResponse: " + createResponse);  
}
```

Example Create an access grant response

```
CreateAccessGrantResponse(  
    CreatedAt=2023-06-07T05:20:26.330Z,  
    AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,  
    AccessGrantArn=arn:aws:s3:us-east-2:44445556666:access-grants/default/grant/  
    a1b2c3d4-5678-90ab-cdef-EXAMPLE33333,  
    Grantee=Grantee(  
        GranteeType=IAM,  
        GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3  
    ),  
    AccessGrantsLocationId=a1b2c3d4-5678-90ab-cdef-EXAMPLEaaaaaa,  
    AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(  
        S3SubPrefix=prefixB*  
    ),  
    GrantScope=s3://DOC-BUCKET-EXAMPLE/prefixB,  
    Permission=READ  
)
```

View a grant

You can view the details of an access grant in your Amazon S3 Access Grants instance by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To view the details of an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.
3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. In the **Grants** section, find the access grant that you want to view. To filter the list of grants, use the search box.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Get the details of an access grant

```
aws s3control get-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

Response:

```
{
    "CreatedAt": "2023-05-31T18:41:34.663000+00:00",
    "AccessGrantId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant-a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "Grantee": {
        "GranteeType": "IAM",
        "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
    },
    "Permission": "READ",
```

```
"AccessGrantsLocationId": "12a6710f-5af8-41f5-b035-0bc795bf1a2b",
"AccessGrantsLocationConfiguration": {
    "S3SubPrefix": "prefixB*"
},
"GrantScope": "s3://amzn-s3-demo-bucket/"
}
```

Example – List all of the access grants in an S3 Access Grants instance

You can optionally use the following parameters to restrict the results to an S3 prefix or AWS Identity and Access Management (IAM) identity:

- **Subprefix** ---grant-scope s3://*bucket-name/prefix**
- **IAM identity** ---grantee-type IAM and --grantee-identifier arn:aws:iam::*123456789000*:role/*accessGrantsConsumerRole*

```
aws s3control list-access-grants \
--account-id 111122223333
```

Response:

```
{
    "AccessGrantsList": [{"CreatedAt": "2023-06-14T17:54:46.542000+00:00",
        "AccessGrantId": "dd8dd089-b224-4d82-95f6-975b4185bbaa",
        "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa",
        "Grantee": {
            "GranteeType": "IAM",
            "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-3"
        },
        "Permission": "READ",
        "AccessGrantsLocationId": "23514a34-ea2e-4ddf-b425-d0d4bfcarda1",
        "GrantScope": "s3://amzn-s3-demo-bucket/prefixA*
    },
    {"CreatedAt": "2023-06-24T17:54:46.542000+00:00",
        "AccessGrantId": "ee8ee089-b224-4d72-85f6-975b4185a1b2",
        "AccessGrantArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2",
        "Grantee": {
            "GranteeType": "IAM",
            "GranteeIdentifier": "arn:aws:iam::111122223333:user/data-consumer-9"
        }
    }
}
```

```
        },
        "Permission": "READ",
        "AccessGrantsLocationId": "12414a34-ea2e-4ddf-b425-d0d4bfccacao0",
        "GrantScope": "s3://amzn-s3-demo-bucket/prefixB*"
    },
}

}
```

Using the REST API

You can use Amazon S3 API operations to view the details of an access grant and list all access grants in an S3 Access Grants instance. For information about the REST API support for managing access grants, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GetAccessGrant](#)
- [ListAccessGrants](#)

Using the AWS SDKs

This section provides examples of how to get the details of an access grant by using the AWS SDKs.

To use the following examples, replace the *user input placeholders* with your own information.

Java

Example – Get the details of an access grant

```
public void getAccessGrant() {
    GetAccessGrantRequest getRequest = GetAccessGrantRequest.builder()
        .accountId("111122223333")
        .accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE22222")
        .build();
    GetAccessGrantResponse getResponse = s3Control.getAccessGrant(getRequest);
    LOGGER.info("GetAccessGrantResponse: " + getResponse);
}
```

Response:

```
GetAccessGrantResponse(
```

```
CreatedAt=2023-06-07T05:20:26.330Z,  
AccessGrantId=a1b2c3d4-5678-90ab-cdef-EXAMPLE22222,  
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/  
grant-fd3a5086-42f7-4b34-9fad-472e2942c70e,  
Grantee=Grantee(  
    GranteeType=IAM,  
    GranteeIdentifier=arn:aws:iam::111122223333:user/data-consumer-3  
,  
    Permission=READ,  
    AccessGrantsLocationId=12a6710f-5af8-41f5-b035-0bc795bf1a2b,  
    AccessGrantsLocationConfiguration=AccessGrantsLocationConfiguration(  
        S3SubPrefix=prefixB*  
,  
        GrantScope=s3://amzn-s3-demo-bucket/  
)
```

Example – List all of the access grants in an S3 Access Grants instance

You can optionally use these parameters to restrict the results to an S3 prefix or IAM identity:

- **Scope** – GrantScope=s3://*bucket-name/prefix**
- **Grantee** – GranteeType=IAM and GranteeIdentifier=
arn:aws:iam::111122223333:role/accessGrantsConsumerRole

```
public void listAccessGrants() {  
    ListAccessGrantsRequest listRequest = ListAccessGrantsRequest.builder()  
        .accountId("111122223333")  
        .build();  
    ListAccessGrantsResponse listResponse = s3Control.listAccessGrants(listRequest);  
    LOGGER.info("ListAccessGrantsResponse: " + listResponse);  
}
```

Response:

```
ListAccessGrantsResponse(  
    AccessGrantsList=[  
        ListAccessGrantEntry(  
            CreatedAt=2023-06-14T17:54:46.540Z,  
            AccessGrantId=dd8dd089-b224-4d82-95f6-975b4185bbaa,
```

```
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/dd8dd089-b224-4d82-95f6-975b4185bbaa,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-3
),
Permission=READ,
AccessGrantsLocationId=23514a34-ea2e-4ddf-b425-d0d4bfcarda1,
GrantScope=s3://amzn-s3-demo-bucket/prefixA
),
ListAccessGrantEntry(
CreatedAt=2023-06-24T17:54:46.540Z,
AccessGrantId=ee8ee089-b224-4d72-85f6-975b4185a1b2,
AccessGrantArn=arn:aws:s3:us-east-2:111122223333:access-grants/default/
grant/ee8ee089-b224-4d72-85f6-975b4185a1b2,
Grantee=Grantee(
GranteeType=IAM, GranteeIdentifier= arn:aws:iam::111122223333:user/data-consumer-9
),
Permission=READ,
AccessGrantsLocationId=12414a34-ea2e-4ddf-b425-d0d4bfcacao0,
GrantScope=s3://amzn-s3-demo-bucket/prefixB*
)
]
)
```

Delete a grant

You can delete access grants from your Amazon S3 Access Grants instance. You can't undo an access grant deletion. After you delete an access grant, the grantee will no longer have access to your Amazon S3 data.

You can delete an access grant by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the S3 console

To delete an access grant

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Access Grants**.

3. On the **S3 Access Grants** page, choose the Region that contains the S3 Access Grants instance that you want to work with.
4. Choose **View details** for the instance.
5. On the details page, choose the **Grants** tab.
6. Search for the grant that you want to delete. When you locate the grant, choose the radio button next to it.
7. Choose **Delete**. A dialog box appears with a warning that your action can't be undone. Choose **Delete** again to delete the grant.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example – Delete an access grant

```
aws s3control delete-access-grant \
--account-id 111122223333 \
--access-grant-id a1b2c3d4-5678-90ab-cdef-EXAMPLE1111

// No response body
```

Using the REST API

For information about the Amazon S3 REST API support for managing access grants, see [DeleteAccessGrant](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides examples of how to delete an access grant by using the AWS SDKs. To use the following example, replace the *user input placeholders* with your own information.

Java

Example – Delete an access grant

```
public void deleteAccessGrant() {
```

```
DeleteAccessGrantRequest deleteRequest = DeleteAccessGrantRequest.builder()  
.accountId("111122223333")  
.accessGrantId("a1b2c3d4-5678-90ab-cdef-EXAMPLE11111")  
.build();  
DeleteAccessGrantResponse deleteResponse =  
    s3Control.deleteAccessGrant(deleteRequest);  
LOGGER.info("DeleteAccessGrantResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantResponse()
```

Getting S3 data using access grants

Grantees who have been given access to S3 data through S3 Access Grants must request temporary credentials from S3 Access Grants, which they use to access the S3 data. For more information, see [Request access to Amazon S3 data through S3 Access Grants](#). Grantees then use the temporary credentials to perform allowable S3 actions on the S3 data. For more information, see [Accessing S3 data using credentials vended by S3 Access Grants](#). Grantees can optionally request a list of their access grants for an AWS account before requesting these credentials. For more information, see [List the caller's access grants](#).

Topics

- [Request access to Amazon S3 data through S3 Access Grants](#)
- [Accessing S3 data using credentials vended by S3 Access Grants](#)
- [List the caller's access grants](#)

Request access to Amazon S3 data through S3 Access Grants

After you use Amazon S3 Access Grants to [create an access grant](#) that gives AWS Identity and Access Management (IAM) principals, your corporate directory identities, or authorized applications access to your S3 data, your grantees can request credentials to access this data.

When an application or AWS service uses the `GetDataAccess` API operation to ask S3 Access Grants for access to your S3 data on behalf of a grantee, S3 Access Grants first verifies that you have granted this identity access to the data. Then, S3 Access Grants uses the [AssumeRole](#) API

operation to obtain a temporary credential token and vends it to the requester. This temporary credential token is an AWS Security Token Service (AWS STS) token.

The `GetDataAccess` request must include the `target` parameter, which specifies the scope of the S3 data that the temporary credentials apply to. This target scope can be the same as the scope of the grant or a subset of that scope, but the target scope must be within the scope of the grant that was given to the requester. The request must also specify the `permission` parameter to indicate the permission level for the temporary credentials, whether `READ`, `WRITE`, or `READWRITE`.

The requester can specify the privilege level of the temporary token in their credential request. Using the `privilege` parameter, the requester can reduce or increase the temporary credentials' scope of access, within the boundaries of the grant scope. The default value of the `privilege` parameter is `Default`, which means that the target scope of the credential returned is the original grant scope. The other possible value for `privilege` is `Minimal`. If the target scope is reduced from the original grant scope, then the temporary credential is de-scoped to match the target scope, as long as the target scope is within the grant scope.

The following table details the effect of the `privilege` parameter on two grants. One grant has the scope `S3://amzn-s3-demo-bucket1/bob/*`, which includes the entire `bob/` prefix in the `amzn-s3-demo-bucket1` bucket. The other grant has the scope `S3://amzn-s3-demo-bucket1/bob/reports/*`, which includes only the `bob/reports/` prefix in the `amzn-s3-demo-bucket1` bucket.

Grant scope	Requested scope	Privilege	Returned scope	Effect
<code>S3://amzn-s3-demo-bucket1/t1/bob/*</code>	<code>amzn-s3-demo-bucket1/t1/bob/*</code>	Default	<code>amzn-s3-demo-bucket1/bob/*</code>	The requester has access to all objects that have key names that start with the prefix <code>bob/</code> in the <code>amzn-s3-demo-bucket1</code> bucket.
<code>S3://amzn-s3-demo-bucket1/t1/bob/</code>	<code>amzn-s3-demo-bucket1/t1/bob/</code>	Minimal	<code>amzn-s3-demo-bucket1/t1/bob/</code>	Without a wild card <code>*</code> character after the prefix name <code>bob/</code> , the requester has access to only the object named

Grant scope	Requested scope	Privilege	Returned scope	Effect
<code>t1 /bob/*</code>				bob/ in the <i>amzn-s3-demo-bucket1</i> bucket. It's not common to have such an object. The requester doesn't have access to any other objects, including those that have key names that start with the bob/ prefix.
<code>S3://amzn-s3-demo-bucket1 t1 /bob/images/*</code>		Minimal	<i>amzn-s3-demo-bucket1 t1 /bob/images/*</i>	The requester has access to all objects that have key names that start with the prefix <i>bob/images/*</i> in the <i>amzn-s3-demo-bucket1</i> bucket.
<code>S3://amzn-s3-demo-bucket1 t1 /bob/reports/*</code>		Default	<i>amzn-s3-demo-bucket1 t1 /bob/reports/*</i>	The requester has access to all objects that have key names that start with the bob/reports prefix in the <i>amzn-s3-demo-bucket1</i> bucket, which is the scope of the matching grant.

Grant scope	Requested scope	Privilege	Returned scope	Effect
S3:// <i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	Minimal	<i>amzn-s3-demo-bucket1</i> / <i>t1/bob/reports/file.txt</i>	The requester has access only to the object with the key name <i>bob/reports/file.txt</i> in the <i>amzn-s3-demo-bucket1</i> bucket. The requester has no access to any other object.

The `durationSeconds` parameter sets the temporary credential's duration, in seconds. The default value is 3600 seconds (1 hour), but the requester (the grantee) can specify a range from 900 seconds (15 minutes) up to 43200 seconds (12 hours). If the grantee requests a value higher than this maximum, the request fails.

Note

In your request for a temporary token, if the location is an object, set the value of the `targetType` parameter in your request to `Object`. This parameter is required only if the location is an object and the privilege level is `Minimal`. If the location is a bucket or a prefix, you don't need to specify this parameter.

For more information, see [GetDataAdapter](#) in the *Amazon Simple Storage Service API Reference*.

You can request temporary credentials by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example Request temporary credentials

Request:

```
aws s3control get-data-access \
--account-id 111122223333 \
--target s3://amzn-s3-demo-bucket/prefixA* \
--permission READ \
--privilege Default \
--region us-east-2
```

Response:

```
{
  "Credentials": {
    "AccessKeyId": "Example-key-id",
    "SecretAccessKey": "Example-access-key",
    "SessionToken": "Example-session-token",
    "Expiration": "2023-06-14T18:56:45+00:00"},
    "MatchedGrantTarget": "s3://amzn-s3-demo-bucket/prefixA**"
}
```

Using the REST API

For information about the Amazon S3 REST API support for requesting temporary credentials from S3 Access Grants, see [GetDataAccess](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the temporary credentials that the grantee uses to access your S3 data. To use this code example, replace the *user input placeholders* with your own information.

Example Get temporary credentials

Request:

```
public void getDataAccess() {  
    GetDataAccessRequest getDataAccessRequest = GetDataAccessRequest.builder()  
        .accountId("111122223333")  
        .permission(Permission.READ)  
        .privilege(Privilege.MINIMAL)  
        .target("s3://amzn-s3-demo-bucket/prefixA*")  
        .build();  
    GetDataAccessResponse getDataAccessResponse =  
        s3Control.getDataAccess(getDataAccessRequest);  
    LOGGER.info("GetDataAccessResponse: " + getDataAccessResponse);  
}
```

Response:

```
GetDataAccessResponse(  
    Credentials=Credentials(  
        AccessKeyId="Example-access-key-id",  
        SecretAccessKey="Example-secret-access-key",  
        SessionToken="Example-session-token",  
        Expiration=2023-06-07T06:55:24Z  
    ))
```

Accessing S3 data using credentials vended by S3 Access Grants

After a grantee [obtains temporary credentials](#) through their access grant, they can use these temporary credentials to call Amazon S3 API operations to access your data.

Grantees can access S3 data by using the AWS Command Line Interface (AWS CLI), the AWS SDKs, and the Amazon S3 REST API. Additionally, you can use the AWS [Python](#) and [Java](#) plugins to call S3 Access Grants

Using the AWS CLI

After the grantee obtains their temporary credentials from S3 Access Grants, they can set up a profile with these credentials to retrieve the data.

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Set up a profile

```
aws configure set aws_access_key_id "$accessKey" --profile access-grants-consumer-access-profile
aws configure set aws_secret_access_key "$secretKey" --profile access-grants-consumer-access-profile
aws configure set aws_session_token "$sessionToken" --profile access-grants-consumer-access-profile
```

To use the following example command, replace the *user input placeholders* with your own information.

Example – Get the S3 data

The grantee can use the [get-object](#) AWS CLI command to access the data. The grantee can also use [put-object](#), [ls](#), and other S3 AWS CLI commands.

```
aws s3api get-object \
--bucket amzn-s3-demo-bucket1 \
--key myprefix \
--region us-east-2 \
--profile access-grants-consumer-access-profile
```

Using the AWS SDKs

This section provides examples of how grantees can access your S3 data by using the AWS SDKs.

Java

For examples of how to get S3 data by using temporary credentials, see how to [get an object by using the AWS SDKs](#) and [Amazon S3 code examples for the AWS SDK for Java 2.x](#).

Supported S3 actions in S3 Access Grants

A grantee can use the temporary credential vended by S3 Access Grants to perform S3 actions on the S3 data they have access to. The following is a list of allowable S3 actions that a grantee can perform. Which actions are allowable depends on the level of permission granted in the access grant, either READ, WRITE, or READWRITE.

Note

In addition to the Amazon S3 permissions listed below, Amazon S3 can call the AWS Key Management Service (AWS KMS) [Decrypt](#) (kms : decrypt) READ permission or the AWS KMS [GenerateDataKey](#) (kms : generateDataKey) WRITE permission. These permissions don't allow direct access to the AWS KMS key.

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:GetObject	GetObject	READ	Object			
s3:GetObjectVersion	GetObject	READ	Object			
s3:GetObjectAcl	GetObjectAcl	READ	Object			
s3:GetObjectVersionAcl	GetObjectAcl	READ	Object			
s3>ListMultipartUploads	ListParts	READ	Object			
s3:PutObject	PutObject , CreateMultipartUpload , UploadPart , UploadPartCopy , CompleteMultipartUpload	WRITE	Object			

S3 IAM action	API action & doc	S3 Access Grants Permission	S3 resource			
s3:PutObjectAcl	PutObjectAcl	WRITE	Object			
s3:PutObjectVersionAcl	PutObjectAcl	WRITE	Object			
s3:DeleteObject	DeleteObject	WRITE	Object			
s3:DeleteObjectVersion	DeleteObject	WRITE	Object			
s3:AbortMultipartUpload	AbortMultipartUpload	WRITE	Object			
s3>ListBucket	HeadBucket , ListObjectsV2 , ListObjects	READ	Bucket			
s3>ListBucketVersions	ListObjectVersions	READ	Bucket			
s3>ListBucketMultipartUploads	ListMultipartUploads	READ	Bucket			

List the caller's access grants

S3 data owners can use S3 Access Grants to create access grants for AWS Identity and Access Management (IAM) identities or for AWS IAM Identity Center corporate directory identities. IAM identities and IAM Identity Center directory identities can in turn use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or directory identity can access through S3 Access Grants.

You can use this feature to build applications that show the data that is accessible to specific end-users. For example, the AWS Storage Browser for S3, an open source UI component that customers use to access S3 buckets, uses this feature to present end-users with the data that they have access to in Amazon S3, based on their S3 Access Grants. Another example is when building an application for browsing, uploading, or downloading data in Amazon S3, you can use this feature to build a tree structure in your application that an end-user could then browse.

The grantee whether an IAM identity, or a corporate directory identity can get a list of their access grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, and the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

To use the following example command, replace the *user input placeholders* with your own information.

Example List a caller's access grants

Request:

```
aws s3control list-caller-access-grants \
--account-id 1112222333 \
--region us-east-2 \
--max-results 5
```

Response:

```
{
```

```
"NextToken": "6J9S...",  
"CallerAccessGrantsList": [  
{  
    "Permission": "READWRITE",  
    "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix1/*",  
    "ApplicationArn": "NA"  
},  
{  
    "Permission": "READWRITE",  
    "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix2/*",  
    "ApplicationArn": "ALL"  
},  
{  
    "Permission": "READWRITE",  
    "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/sub-prefix3/*",  
    "ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"  
}  
]
```

Example List a caller's access grants for a bucket

You can narrow the scope of the results using the grantscope parameter.

Request:

```
aws s3control list-caller-access-grants \  
--account-id 111122223333 \  
--region us-east-2 \  
--grant-scope "s3://amzn-s3-demo-bucket"\" \  
--max-results 1000
```

Response:

```
{  
    "NextToken": "6J9S...",  
    "CallerAccessGrantsList": [  
        {  
            "Permission": "READ",  
            "GrantScope": "s3://amzn-s3-demo-bucket*",  
            "ApplicationArn": "ALL"
```

```
},
{
  "Permission": "READ",
  "GrantScope": "s3://amzn-s3-demo-bucket/prefix1/*",
  "ApplicationArn": "arn:aws:sso::111122223333:application/ssoins-
ssoins-1234567890abcdef/apl-abcd1234a1b2c3d"
}
]
```

Using the REST API

For information about the Amazon S3 REST API support for getting a list of the API caller's access grants, see [ListCallerAccessGrants](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

This section provides an example of how grantees request temporary credentials from S3 Access Grants by using the AWS SDKs.

Java

The following code example returns the API caller's access grants to the S3 data of a particular AWS account. To use this code example, replace the *user input placeholders* with your own information.

Example List a caller's access grants

Request:

```
Public void ListCallerAccessGrants() {
    ListCallerAccessGrantsRequest listRequest = ListCallerAccessGrantsRequest.builder()
        .withMaxResults(1000)
        .withGrantScope("s3://")
        .accountId("111122223333");
    ListCallerAccessGrantsResponse listResponse =
        s3control.listCallerAccessGrants(listRequest);
    LOGGER.info("ListCallerAccessGrantsResponse: " + listResponse);
}
```

Response:

```
ListCallerAccessGrantsResponse(  
    CallerAccessGrantsList=[  
        ListCallerAccessGrantsEntry(  
            S3Prefix=s3://amzn-s3-demo-bucket/prefix1,  
            Permission=READ,  
            ApplicationArn=ALL  
        )  
    ])
```

S3 Access Grants cross-account access

With S3 Access Grants, you can grant Amazon S3 data access to the following:

- AWS Identity and Access Management (IAM) identities within your account
- IAM identities in other AWS accounts
- Directory users or groups in your AWS IAM Identity Center instance

First, configure cross-account access for the other account. This includes granting access to your S3 Access Grants instance by using a resource policy. Then, grant access to your S3 data (buckets, prefixes, or objects) by using grants.

After you configure cross-account access, the other account can request temporary access credentials to your Amazon S3 data from S3 Access Grants. The following image shows the user flow for cross-account S3 access through S3 Access Grants:

1. Users or applications in a second account (B) request credentials from the S3 Access Grants instance in your account (A), where the Amazon S3 data is stored. For more information, see [Request access to Amazon S3 data through S3 Access Grants](#).
2. The S3 Access Grants instance in your account (A) returns temporary credentials if there is a grant that gives the second account access to your Amazon S3 data. For more information on access grants, see [Working with grants in S3 Access Grants](#).
3. Users or applications in the second account (B) use the S3 Access Grants-vended credentials to access the S3 data in your account (A).

Configuring S3 Access Grants cross-account access

To grant cross-account S3 access through S3 Access Grants, follow these steps:

- **Step 1:** Configure an S3 Access Grants instance in your account, for example, account ID 111122223333, where the S3 data is stored.
- **Step 2:** Configure the resource policy for the S3 Access Grants instance in your account 111122223333 to give access to the second account, for example, account ID 444455556666.
- **Step 3:** Configure the IAM permissions for the IAM Principal in the second account 444455556666 to request credentials from the S3 Access Grants instance in your account 111122223333.
- **Step 4:** Create a grant in your account 111122223333 that gives the IAM Principal in the second account 444455556666 access to some of the S3 data in your account 111122223333.

Step 1: Configure an S3 Access Grants instance in your account

First, you must have an S3 Access Grants instance in your account 111122223333 to manage access to your Amazon S3 data. You must create an S3 Access Grants instance in each AWS Region where the S3 data that you want to share is stored. If you are sharing data in more than one AWS Region, then repeat each of these configuration steps for each AWS Region. If you already have an S3 Access Grants instance in the AWS Region where your S3 data is stored, proceed to the next step. If you haven't configured an S3 Access Grants instance, see [Working with S3 Access Grants instances](#) to complete this step.

Step 2: Configure the resource policy for your S3 Access Grants instance to grant cross-account access

After you create an S3 Access Grants instance in your account 111122223333 for cross-account access, configure the resource-based policy for the S3 Access Grants instance in your account 111122223333 to grant cross-account access. The S3 Access Grants instance itself supports resource-based policies. With the correct resource-based policy in place, you can grant access for AWS Identity and Access Management (IAM) users or roles from other AWS accounts to your S3 Access Grants instance. Cross-account access only grants these permissions (actions):

- `s3:GetAccessGrantsInstanceForPrefix` — the user, role, or app can retrieve the S3 Access Grants instance that contains a particular prefix.
- `s3>ListAccessGrants`
- `s3>ListAccessLocations`
- `s3>ListCallerAccessGrants`

- `s3:GetDataAccess` — the user, role, or app can request temporary credentials based on the access you were granted through S3 Access Grants. Use these credentials to access the S3 data to which you have been granted access.

You can choose which of these permissions to include in the resource policy. This resource policy on the S3 Access Grants instance is a normal resource-based policy and supports everything that the [IAM policy language](#) supports. In the same policy, you can grant access to specific IAM identities in your account 111122223333, for example, by using the `aws:PrincipalArn` condition, but you don't have to do that with S3 Access Grants. Instead, within your S3 Access Grants instance, you can create grants for individual IAM identities from your account, as well as for the other account. By managing each access grant through S3 Access Grants, you can scale your permissions.

If you already use [AWS Resource Access Manager](#) (AWS RAM), you can use it to share your [`s3:AccessGrants`](#) resources with other accounts or within your organization. See [Working with shared AWS resources](#) for more information. If you don't use AWS RAM, you can also add the resource policy by using the S3 Access Grants API operations or the AWS Command Line Interface (AWS CLI).

Using the S3 console

We recommend that you use the AWS Resource Access Manager (AWS RAM) Console to share your `s3:AccessGrants` resources with other accounts or within your organization. To share S3 Access Grants cross-account, do the following:

To configure the S3 Access Grants instance resource policy:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Select the AWS Region from the AWS Region selector.
3. From the left navigation pane, select **Access Grants**.
4. On the Access Grants instance page, in the **Instance in this account** section, select **Share instance**. This will redirect you to the AWS RAM Console.
5. Select **Create resource share**.
6. Follow the AWS RAM steps to create the resource share. For more information, see [Creating a resource share in AWS RAM](#).

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can add the resource policy by using the `put-access-grants-instance-resource-policy` CLI command.

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- `s3>ListAccessGrants`
- `s3>ListAccessGrantsLocations`
- `s3:GetDataAccess`
- `s3:GetAccessGrantsInstanceForPrefix`

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the Resource, and the second account 444455556666 as the Principal. To use the following example, replace the *user input placeholders* with your own information.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "444455556666"  
      },  
      "Action": [  
        "s3>ListAccessGrants",  
        "s3>ListAccessGrantsLocations",  
        "s3:GetDataAccess",  
        "s3:GetAccessGrantsInstanceForPrefix"  
      ],  
      "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
    } ]  
}
```

To add or update the S3 Access Grants instance resource policy, use the following command. When you use the following example command, replace the *user input placeholders* with your own information.

Example Add or update the S3 Access Grants instance resource policy

```
aws s3control put-access-grants-instance-resource-policy \
--account-id 111122223333 \
--policy file://resourcePolicy.json \
--region us-east-2
{
    "Policy": "{\n        \"Version\": \"2012-10-17\", \n        \"Statement\": [{\n            \"Effect\": \"Allow\", \n            \"Principal\": {\"AWS\": \"44445556666\"},\n            \"Action\": [\n                \"s3>ListAccessGrants\", \n                \"s3>ListAccessGrantsLocations\", \n                \"s3>GetDataAccess\", \n                \"s3>GetAccessGrantsInstanceForPrefix\", \n                \"s3>ListCallerAccessGrants\"\n            ],\n            \"Resource\": \"arn:aws:s3:us-east-2:111122223333:access-grants/default\"\n        }],\n        \"CreatedAt\": \"2023-06-16T00:07:47.473000+00:00\"\n    }"
}
```

Example Get an S3 Access Grants resource policy

You can also use the CLI to get or delete a resource policy for an S3 Access Grants instance.

To get an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-access-grants-instance-resource-policy \
--account-id 111122223333 \
--region us-east-2
```

```
{  
"Policy": "{\"Version\":\"2012-10-17\"}, \"Statement\":[{\"Effect\":\"Allow  
\", \"Principal\":{\"AWS\":\"arn:aws:iam::111122223333:root\"}, \"Action\":  
[\"s3>ListAccessGrants\", \"s3>ListAccessGrantsLocations\", \"s3:GetDataAccess\",  
\"s3:GetAccessGrantsInstanceForPrefix\", \"s3>ListCallerAccessGrants\"], \"Resource\":  
\"arn:aws:  
s3:us-east-2:111122223333:access-grants/default\"]}]}",  
"CreatedAt": "2023-06-16T00:07:47.473000+00:00"  
}
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following example command. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-access-grants-instance-resource-policy \  
--account-id 111122223333 \  
--region us-east-2  
  
// No response body
```

Using the REST API

You can add the resource policy by using the [PutAccessGrantsInstanceResourcePolicy API](#).

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- s3>ListAccessGrants
- s3>ListAccessGrantsLocations
- s3:GetDataAccess
- s3:GetAccessGrantsInstanceForPrefix

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the Resource, and the second account 444455556666 as the Principal. To use the following example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "44445556666"  
            },  
            "Action": [  
                "s3>ListAccessGrants",  
                "s3>ListAccessGrantsLocations",  
                "s3>GetDataAccess",  
                "s3>GetAccessGrantsInstanceForPrefix"  
            ],  
            "Resource": "arn:aws:s3:us-east-2:11122223333:access-grants/default"  
        } ]  
    }  
}
```

You can then use the [PutAccessGrantsInstanceResourcePolicy API](#) to configure the policy.

For information on the REST API support to update, get, or delete a resource policy for an S3 Access Grants instance, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [PutAccessGrantsInstanceResourcePolicy](#)
- [GetAccessGrantsInstanceResourcePolicy](#)
- [DeleteAccessGrantsInstanceResourcePolicy](#)

Using the AWS SDKs

This section provides you with the AWS SDK examples of how to configure your S3 Access Grants resource policy to grant a second AWS account access to some of your S3 data.

Java

Add, update, get, or delete a resource policy to manage cross-account access to your S3 Access Grants instance.

Example Add or update an S3 Access Grants instance resource policy

If you want to grant cross-account access for the S3 Access Grants instance in your account 111122223333 to the second account 444455556666, the resource policy for the S3 Access Grants instance in your account 111122223333 should give the second account 444455556666 permission to perform the following actions:

- s3>ListAccessGrants
- s3>ListAccessGrantsLocations
- s3:GetDataAccess
- s3:GetAccessGrantsInstanceForPrefix

In the S3 Access Grants instance resource policy, specify the ARN of your S3 Access Grants instance as the Resource, and the second account 444455556666 as the Principal. To use the following example, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "444455556666"  
            },  
            "Action": [  
                "s3>ListAccessGrants",  
                "s3>ListAccessGrantsLocations",  
                "s3:GetDataAccess",  
                "s3:GetAccessGrantsInstanceForPrefix"  
            ],  
            "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
        }  
    ]  
}
```

To add or update an S3 Access Grants instance resource policy, use the following code example:

```
public void putAccessGrantsInstanceResourcePolicy() {  
    PutAccessGrantsInstanceResourcePolicyRequest putRequest =  
        PutAccessGrantsInstanceResourcePolicyRequest.builder()  
            .accountId(111122223333)
```

```
.policy(RESOURCE_POLICY)
.build();
PutAccessGrantsInstanceResourcePolicyResponse putResponse =
s3Control.putAccessGrantsInstanceResourcePolicy(putRequest);
LOGGER.info("PutAccessGrantsInstanceResourcePolicyResponse: " + putResponse);
}
```

Response:

```
PutAccessGrantsInstanceResourcePolicyResponse(
Policy={
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Principal": {
"AWS": "444455556666"
},
>Action": [
"s3>ListAccessGrants",
"s3>ListAccessGrantsLocations",
"s3>GetDataAccess",
"s3>GetAccessGrantsInstanceForPrefix",
"s3>ListCallerAccessGrants"
],
"Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
}]
}
)
```

Example Get an S3 Access Grants resource policy

To get an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void getAccessGrantsInstanceResourcePolicy() {
GetAccessGrantsInstanceResourcePolicyRequest getRequest =
GetAccessGrantsInstanceResourcePolicyRequest.builder()
.accountId(111122223333)
.build();
GetAccessGrantsInstanceResourcePolicyResponse getResponse =
s3Control.getAccessGrantsInstanceResourcePolicy(getRequest);
```

```
LOGGER.info("GetAccessGrantsInstanceResourcePolicyResponse: " + getResponse);  
}
```

Response:

```
GetAccessGrantsInstanceResourcePolicyResponse(  
    Policy={"Version":"2012-10-17","Statement":[{"Effect":"Allow","Principal":  
        {"AWS":"arn:aws:iam::44445556666:root"}, "Action":  
        ["s3>ListAccessGrants", "s3>ListAccessGrantsLocations", "s3:GetDataAccess", "s3:GetAccessGrants"],  
        "CreatedAt":2023-06-15T22:54:44.319Z  
    })
```

Example Delete an S3 Access Grants resource policy

To delete an S3 Access Grants resource policy, use the following code example. To use the following example command, replace the *user input placeholders* with your own information.

```
public void deleteAccessGrantsInstanceResourcePolicy() {  
    DeleteAccessGrantsInstanceResourcePolicyRequest deleteRequest =  
    DeleteAccessGrantsInstanceResourcePolicyRequest.builder()  
        .accountId(111122223333)  
        .build();  
    DeleteAccessGrantsInstanceResourcePolicyResponse deleteResponse =  
    s3Control.putAccessGrantsInstanceResourcePolicy(deleteRequest);  
    LOGGER.info("DeleteAccessGrantsInstanceResourcePolicyResponse: " + deleteResponse);  
}
```

Response:

```
DeleteAccessGrantsInstanceResourcePolicyResponse()
```

Step 3: Grant IAM identities in a second account permission to call the S3 Access Grants instance in your account

After the owner of the Amazon S3 data has configured the cross-account policy for the S3 Access Grants instance in account 111122223333, the owner of the second account 44445556666 must create an identity-based policy for its IAM users or roles, and the owner must give them access to

the S3 Access Grants instance. In the identity-based policy, include one or more of the following actions, depending on what's granted in the S3 Access Grants instance resource policy and the permissions you want to grant:

- s3>ListAccessGrants
- s3>ListAccessGrantsLocations
- s3:GetDataAccess
- s3:GetAccessGrantsInstanceForPrefix
- s3>ListCallerAccessGrants

Following the [AWS cross-account access pattern](#), the IAM users or roles in the second account 44445556666 must explicitly have one or more of these permissions. For example, grant the s3:GetDataAccess permission so that the IAM user or role can call the S3 Access Grants instance in account 111122223333 to request credentials.

To use this example command, replace the *user input placeholders* with your own information.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "s3:GetDataAccess",  
      ],  
      "Resource": "arn:aws:s3:us-east-2:111122223333:access-grants/default"  
    }  
  ]  
}
```

For information on editing IAM identity-based policy, see [Editing IAM policies](#) in the *AWS Identity and Access Management guide*.

Step 4: Create a grant in the S3 Access Grants instance of your account that gives the IAM identity in the second account access to some of your S3 data

For the final configuration step, you can create a grant in the S3 Access Grants instance in your account 111122223333 that gives access to the IAM identity in the second account 44445556666

to some of the S3 data in your account. You can do this by using the Amazon S3 Console, CLI, API, and SDKs. For more information, see [Create grants](#).

In the grant, specify the AWS ARN of the IAM identity from the second account, and specify which location in your S3 data (a bucket, prefix, or object) that you are granting access to. This location must already be registered with your S3 Access Grants instance. For more information, see [Register a location](#). You can optionally specify a subprefix. For example, if the location you are granting access to is a bucket, and you want to limit the access further to a specific object in that bucket, then pass the object key name in the S3SubPrefix field. Or if you want to limit access to the objects in the bucket with key names that start with a specific prefix, such as 2024-03-research-results/, then pass S3SubPrefix=2024-03-research-results/.

The following is an example CLI command for creating an access grant for an identity in the second account. See [Create grants](#) for more information. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-access-grant \
--account-id 111122223333 \
--access-grants-location-id default \
--access-grants-location-configuration S3SubPrefix=prefixA* \
--permission READ \
--grantee GranteeType=IAM,GranteeIdentifier=arn:aws:iam::444455556666:role/data-consumer-1
```

After configuring cross-account access, the user or role in the second account can do the following:

- Calls `ListAccessGrantsInstances` to list the S3 Access Grants instances shared with it through AWS RAM. For more information, see [Get the details of an S3 Access Grants instance](#).
- Requests temporary credentials from S3 Access Grants. For more information on how to make these requests, see [Request access to Amazon S3 data through S3 Access Grants](#).

Using AWS tags with S3 Access Grants

Tags in Amazon S3 Access Grants have similar characteristics to [object tags](#) in Amazon S3. Each tag is a key-value pair. The resources in S3 Access Grants that you can tag are S3 Access Grants [instances](#), [locations](#), and [grants](#).

Note

Tagging in S3 Access Grants uses different API operations than object tagging. S3 Access Grants uses the [TagResource](#), [UntagResource](#), and [ListTagsForResource](#) API operations, where a resource can be either an S3 Access Grants instance, a registered location, or an access grant.

Similar to [object tags](#), the following limitations apply:

- You can add tags to new S3 Access Grants resources when you create them, or you can add tags to existing resources.
- You can associate up to 10 tags with a resource. If multiple tags are associated with the same resource, they must have unique tag keys.
- A tag key can be up to 128 Unicode characters in length, and tag values can be up to 256 Unicode characters in length. Tags are internally represented in UTF-16. In UTF-16, characters consume either 1 or 2 character positions.
- The keys and values are case sensitive.

For more information about tag restrictions, see [User-defined tag restrictions](#) in the *AWS Billing User Guide*.

You can tag resources in S3 Access Grants by using the AWS Command Line Interface (AWS CLI), the Amazon S3 REST API, or the AWS SDKs.

Using the AWS CLI

To install the AWS CLI, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

You can tag an S3 Access Grants resource when you create it or after you have created it. The following examples show how you tag or untag an S3 Access Grants instance. You can perform similar operations for registered locations and access grants.

To use the following example commands, replace the *user input placeholders* with your own information.

Example – Create an S3 Access Grants instance with tags

```
aws s3control create-access-grants-instance \
```

```
--account-id 111122223333 \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey1,Value=tagValue1
```

Response:

```
{
  "CreatedAt": "2023-10-25T01:09:46.719000+00:00",
  "AccessGrantsInstanceId": "default",
  "AccessGrantsInstanceArn": "arn:aws:s3:us-east-2:111122223333:access-grants/default"
}
```

Example – Tag an already created S3 Access Grants instance

```
aws s3control tag-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2 \
--tags Key=tagKey2,Value=tagValue2
```

Example – List tags for the S3 Access Grants instance

```
aws s3control list-tags-for-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2
```

Response:

```
{
  "Tags": [
    {
      "Key": "tagKey1",
      "Value": "tagValue1"
    },
    {
      "Key": "tagKey2",
      "Value": "tagValue2"
    }
  ]
}
```

```
    }
]
}
```

Example – Untag the S3 Access Grants instance

```
aws s3control untag-resource \
--account-id 111122223333 \
--resource-arn "arn:aws:s3:us-east-2:111122223333:access-grants/default" \
--profile access-grants-profile \
--region us-east-2 \
--tag-keys "tagKey2"
```

Using the REST API

You can use the Amazon S3 API to tag, untag, or list tags for an S3 Access Grants instance, registered location, or access grant. For information about the REST API support for managing S3 Access Grants tags, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [TagResource](#)
- [UntagResource](#)
- [ListTagsForResource](#)

S3 Access Grants limitations

[S3 Access Grants](#) has the following limitations:

 **Note**

If your use case exceeds these limitations, [contact AWS support](#) to request higher limits.

S3 Access Grants instance

You can create **1 S3 Access Grants instance** per AWS Region per account. See [Create an S3 Access Grants instance](#).

S3 Access Grants location

You can register **1,000 S3 Access Grants locations** per S3 Access Grants instance. See [Register an S3 Access Grants location](#).

Grant

You can create **100,000 grants** per S3 Access Grants instance. See [Create a grant](#).

S3 Access Grants AWS Regions

S3 Access Grants is currently available in the following AWS Regions:

AWS Region code	AWS Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
af-south-1	Africa (Cape Town)
ap-east-1	Asia Pacific (Hong Kong)
ap-northeast-1	Asia Pacific (Tokyo)
ap-northeast-2	Asia Pacific (Seoul)
ap-northeast-3	Asia Pacific (Osaka)
ap-south-1	Asia Pacific (Mumbai)
ap-south-2	Asia Pacific (Hyderabad)
ap-southeast-1	Asia Pacific (Singapore)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-3	Asia Pacific (Jakarta)
ap-southeast-4	Asia Pacific (Melbourne)
ca-central-1	Canada (Central)

AWS Region code	AWS Region name
ca-west-1	Canada West (Calgary)
eu-central-1	Europe (Frankfurt)
eu-central-2	Europe (Zurich)
eu-north-1	Europe (Stockholm)
eu-south-1	Europe (Milan)
eu-south-2	Europe (Spain)
eu-west-1	Europe (Ireland)
eu-west-2	Europe (London)
eu-west-3	Europe (Paris)
il-central-1	Israel (Tel Aviv)
me-central-1	Middle East (UAE)
me-south-1	Middle East (Bahrain)
sa-east-1	South America (São Paulo)

S3 Access Grants integrations

S3 Access Grants can be used with the following AWS services and features. This page will be updated as new integrations become available.

Amazon Athena

[Using IAM Identity Center enabled Athena workgroups](#)

Amazon EMR

[Launch an Amazon EMR cluster with S3 Access Grants](#)

Amazon EMR on EKS

[Launch an Amazon EMR on EKS cluster with S3 Access Grants](#)

Amazon EMR Serverless application

[Launch an Amazon EMR Serverless application with S3 Access Grants](#)

Amazon Redshift

[Amazon Redshift integration with Amazon S3 Access Grants](#)

Amazon SageMaker AI Studio

[Using Amazon S3 Access Grants with Amazon SageMaker AI Studio and the SDK for Python \(Boto3\) plugin](#)

Using S3 Access Grants in Amazon SageMaker AI Studio notebooks is now easier when using the SDK for Python (Boto3) plugin. Set up access grants for IAM principals and AWS IAM Identity Center directory users, beforehand. Although Amazon SageMaker AI Studio does not natively support identity provider directory users, you can write custom Python code, using the plugin that allows these identities to access S3 data via S3 Access Grants. The data access is taking place with the help of the plugin and not through Amazon SageMaker AI.

AWS Glue

[Amazon S3 Access Grants with AWS Glue](#)

AWS IAM Identity Center

[Trusted identity propagation across applications](#)

AWS Transfer Family

[Configure Amazon S3 Access Grants for AWS Transfer Family](#)

Storage Browser for S3

[Managing data access at scale using Storage Browser for S3](#)

Open source Python frameworks

[Amazon S3 Access Grants now integrates with open source Python frameworks](#)

Managing access with ACLs

Access control lists (ACLs) are one of the resource-based options that you can use to manage access to your buckets and objects. You can use ACLs to grant basic read/write permissions to other AWS accounts. There are limits to managing permissions using ACLs.

For example, you can grant permissions only to other AWS accounts; you cannot grant permissions to users in your account. You cannot grant conditional permissions, nor can you explicitly deny permissions. ACLs are suitable for specific scenarios. For example, if a bucket owner allows other AWS accounts to upload objects, permissions to these objects can only be managed using object ACL by the AWS account that owns the object.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

For more information about ACLs, see the following topics.

Topics

- [Access control list \(ACL\) overview](#)
- [Configuring ACLs](#)

- [Policy examples for ACLs](#)

Access control list (ACL) overview

Amazon S3 access control lists (ACLs) enable you to manage access to buckets and objects. Each bucket and object has an ACL attached to it as a subresource. It defines which AWS accounts or groups are granted access and the type of access. When a request is received against a resource, Amazon S3 checks the corresponding ACL to verify that the requester has the necessary access permissions.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported.

When you create a bucket or an object, Amazon S3 creates a default ACL that grants the resource owner full control over the resource. This is shown in the following sample bucket ACL (the default object ACL has the same structure):

Example

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>*** Owner-Canonical-User-ID ***</ID>
    <DisplayName>owner-display-name</DisplayName>
  </Owner>
  <AccessControlList>
    <Grant>
      <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                xsi:type="Canonical User">
        <ID>*** Owner-Canonical-User-ID ***</ID>
        <DisplayName>display-name</DisplayName>
      </Grantee>
      <Permission>FULL_CONTROL</Permission>
    </Grant>
  </AccessControlList>
</AccessControlPolicy>
```

The sample ACL includes an `Owner` element that identifies the owner by the AWS account's canonical user ID. For instructions on finding your canonical user ID, see [Finding an AWS account canonical user ID](#). The `Grant` element identifies the grantee (either an AWS account or a predefined group) and the permission granted. This default ACL has one `Grant` element for the owner. You grant permissions by adding `Grant` elements, with each grant identifying the grantee and the permission.

 **Note**

An ACL can have up to 100 grants.

Topics

- [Who is a grantee?](#)
- [What permissions can I grant?](#)
- [aclRequired values for common Amazon S3 requests](#)
- [Sample ACL](#)
- [Canned ACL](#)

Who is a grantee?

A grantee can be an AWS account or one of the predefined Amazon S3 groups. You grant permission to an AWS account using the email address or the canonical user ID. However, if you provide an email address in your grant request, Amazon S3 finds the canonical user ID for that account and adds it to the ACL. The resulting ACLs always contain the canonical user ID for the AWS account, not the email address of the AWS account.

When you grant access rights, you specify each grantee as a `type="value"` pair, where `type` is one of the following:

- `id` – If the value specified is the canonical user ID of an AWS account
- `uri` – If you are granting permissions to a predefined group
- `emailAddress` – If the value specified is the email address of an AWS account

Important

Using email addresses to specify a grantee is only supported in the following AWS Regions:

- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Ireland)
- South America (São Paulo)

For a list of all the Amazon S3 supported regions and endpoints, see [Regions and Endpoints](#) in the *Amazon Web Services General Reference*.

Example Example: Email address

For example, the following `x-amz-grant-read` header grants the AWS accounts identified by email addresses permissions to read object data and its metadata:

```
x-amz-grant-read: emailAddress="xyz@example.com", emailAddress="abc@example.com"
```

Warning

When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see [Creating a Role to Delegate Permissions to an IAM User](#) in the *IAM User Guide*.

Finding an AWS account canonical user ID

The canonical user ID is associated with your AWS account. This ID is a long string of characters, such as:

79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be

For information about how to find the canonical user ID for your account, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

You can also look up the canonical user ID of an AWS account by reading the ACL of a bucket or an object to which the AWS account has access permissions. When an individual AWS account is granted permissions by a grant request, a grant entry is added to the ACL with the account's canonical user ID.

Note

If you make your bucket public (not recommended), any unauthenticated user can upload objects to the bucket. These anonymous users don't have an AWS account. When an anonymous user uploads an object to your bucket, Amazon S3 adds a special canonical user ID (65a011a29cdf8ec533ec3d1ccaae921c) as the object owner in the ACL. For more information, see [Amazon S3 bucket and object ownership](#).

Amazon S3 predefined groups

Amazon S3 has a set of predefined groups. When granting account access to a group, you specify one of the Amazon S3 URIs instead of a canonical user ID. Amazon S3 provides the following predefined groups:

- **Authenticated Users group** – Represented by `http://acs.amazonaws.com/groups/global/AuthenticatedUsers`.

This group represents all AWS accounts. **Access permission to this group allows any AWS account to access the resource.** However, all requests must be signed (authenticated).

 **Warning**

When you grant access to the **Authenticated Users group**, any AWS authenticated user in the world can access your resource.

- **All Users group** – Represented by `http://acs.amazonaws.com/groups/global/AllUsers`.

Access permission to this group allows anyone in the world access to the resource. The requests can be signed (authenticated) or unsigned (anonymous). Unsigned requests omit the Authentication header in the request.

 **Warning**

We highly recommend that you never grant the **All Users group** WRITE, WRITE_ACP, or FULL_CONTROL permissions. For example, although WRITE permissions deny non-owners the ability to overwrite or delete existing objects, WRITE permissions still allow anyone to store objects in your bucket, for which you are billed. For more details about these permissions, see the following section [What permissions can I grant?](#).

- **Log Delivery group** – Represented by `http://acs.amazonaws.com/groups/s3/LogDelivery`.

WRITE permission on a bucket enables this group to write server access logs (see [Logging requests with server access logging](#)) to the bucket.

 **Note**

When using ACLs, a grantee can be an AWS account or one of the predefined Amazon S3 groups. However, the grantee cannot be an IAM user. For more information about AWS users and permissions within IAM, see [Using AWS Identity and Access Management](#).

What permissions can I grant?

The following table lists the set of permissions that Amazon S3 supports in an ACL. The set of ACL permissions is the same for an object ACL and a bucket ACL. However, depending on the context (bucket ACL or object ACL), these ACL permissions grant permissions for specific buckets or object operations. The table lists the permissions and describes what they mean in the context of objects and buckets.

For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

Permission	When granted on a bucket	When granted on an object
READ	Allows grantee to list the objects in the bucket	Allows grantee to read the object data and its metadata
WRITE	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects	Not applicable
READ_ACP	Allows grantee to read the bucket ACL	Allows grantee to read the object ACL
WRITE_ACP	Allows grantee to write the ACL for the applicable bucket	Allows grantee to write the ACL for the applicable object
FULL_CONTROL	Allows grantee the READ, WRITE, READ_ACP, and WRITE_ACP permissions on the bucket	Allows grantee the READ, READ_ACP, and WRITE_ACP permissions on the object

Warning

Use caution when granting access permissions to your S3 buckets and objects. For example, granting WRITE access to a bucket allows the grantee to create objects in the bucket. We highly recommend that you read through the entire [Access control list \(ACL\) overview](#) section before granting permissions.

Mapping of ACL permissions and access policy permissions

As shown in the preceding table, an ACL allows only a finite set of permissions, compared to the number of permissions that you can set in an access policy (see [Policy actions for Amazon S3](#)). Each of these permissions allows one or more Amazon S3 operations.

The following table shows how each ACL permission maps to the corresponding access policy permissions. As you can see, access policy allows more permissions than an ACL does. You use ACLs primarily to grant basic read/write permissions, similar to file system permissions. For more information about when to use an ACL, see [Identity and Access Management for Amazon S3](#).

For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
READ	s3>ListBucket , s3>ListBucketVersions , and s3>ListBucketMultipartUploads	s3:GetObject and s3:GetObjectVersion
WRITE	s3:PutObject Bucket owner can create, overwrite, and delete any object in the bucket, and object owner has FULL_CONTROL over their object. In addition, when the grantee is the bucket owner, granting WRITE permission in a bucket ACL allows the s3>DeleteObjectVersion action to be performed on any version in that bucket.	Not applicable
READ_ACP	s3:GetBucketAcl	s3:GetObjectAcl and s3:GetObjectVersionAcl

ACL permission	Corresponding access policy permissions when the ACL permission is granted on a bucket	Corresponding access policy permissions when the ACL permission is granted on an object
WRITE_ACP	s3:PutBucketAcl	s3:PutObjectAcl and s3:PutObjectVersionAcl
FULL_CONTROL	Equivalent to granting READ, WRITE, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.	Equivalent to granting READ, READ_ACP, and WRITE_ACP ACL permissions. Accordingly, this ACL permission maps to a combination of corresponding access policy permissions.

Condition keys

When you grant access policy permissions, you can use condition keys to constrain the value for the ACL on an object using a bucket policy. The following context keys correspond to ACLs. You can use these context keys to mandate the use of a specific ACL in a request:

- `s3:x-amz-grant-read` - Require read access.
- `s3:x-amz-grant-write` - Require write access.
- `s3:x-amz-grant-read-acp` - Require read access to the bucket ACL.
- `s3:x-amz-grant-write-acp` - Require write access to the bucket ACL.
- `s3:x-amz-grant-full-control` - Require full control.
- `s3:x-amz-acl` - Require a [Canned ACL](#).

For example policies that involve ACL-specific headers, see [Granting s3:PutObject permission with a condition requiring the bucket owner to get full control](#). For a complete list of Amazon S3 specific condition keys, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

aclRequired values for common Amazon S3 requests

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. The `aclRequired` value that appears in CloudTrail or Amazon S3 server access logs depends on which operations were called and certain information about the requester, object owner, and bucket owner. If no ACLs were required, or if you are setting the `bucket-owner-full-control` canned ACL, or if the requests are allowed by your bucket policy, the `aclRequired` value string is `"-"` in Amazon S3 server access logs and is absent in CloudTrail.

The following tables list the expected `aclRequired` values in CloudTrail or Amazon S3 server access logs for the various Amazon S3 API operations. You can use this information to understand which Amazon S3 operations depend on ACLs for authorization. In the following tables, A, B, and C represent the different accounts associated with the requester, object owner, and bucket owner. Entries with an asterisk (*) indicate any of accounts A, B, or C.

 **Note**

PutObject operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a `bucket-owner-full-control` ACL. A null value for `aclRequired` indicates that `aclRequired` is absent in AWS CloudTrail logs.

The following table shows the `aclRequired` values for CloudTrail.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	A	A	Yes or No	null	Same-account access
GetObject	A	B	A	Yes or No	null	Same-account access with bucket

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
						owner enforced
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	A	B	No	Yes	Cross-account access relies on ACL
GetObject	A	A	B	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
GetObject	A	B	C	Yes	null	Cross-account access granted by bucket policy
GetObject	A	B	C	No	Yes	Cross-account access relies on ACL
PutObject	A	Not applicable	A	Yes or No	null	Same-account access
PutObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
PutObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
PutObject with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
ListObjects	A	Not applicable	A	Yes or No	null	Same-account access
ListObjects	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
ListObjects	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
DeleteObject	A	Not applicable	A	Yes or No	null	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
DeleteObject	A	Not applicable	B	Yes	null	Cross-account access granted by bucket policy
DeleteObject	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
PutObjectAcl	*	*	*	Yes or No	Yes	Request grants ACL
PutBucketAcl	*	Not applicable	*	Yes or No	Yes	Request grants ACL

 **Note**

REST.PUT.OBJECT operations in the following table, unless specified otherwise, indicate requests that do not set an ACL, unless the ACL is a bucket-owner-full-control ACL. An aclRequired value string of "-" indicates a null value in Amazon S3 server access logs.

The following table shows the aclRequired values for Amazon S3 server access logs.

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.GET.OBJECT	A	A	A	Yes or No	-	Same-account access
REST.GET.OBJECT	A	B	A	Yes or No	-	Same-account access with bucket owner enforced
REST.GET.OBJECT	A	A	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	A	B	No	Yes	Cross-account access relies on ACL
REST.GET.OBJECT	A	B	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	B	B	No	Yes	Cross-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
						relies on ACL
REST.GET.OBJECT	A	B	C	Yes	-	Cross-account access granted by bucket policy
REST.GET.OBJECT	A	B	C	No	Yes	Cross-account access relies on ACL
REST.PUT.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access
REST.PUT.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.PUT.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.PUT.OBJECT with an ACL (except for bucket-owner-full-control)	*	Not applicable	*	Yes or No	Yes	Request grants ACL
REST.GET.BUCKET	A	Not applicable	A	Yes or No	-	Same-account access
REST.GET.BUCKET	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.GET.BUCKET	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.DELETE.OBJECT	A	Not applicable	A	Yes or No	-	Same-account access

Operation name	Requester	Object owner	Bucket owner	Bucket policy grants access	aclRequired value	Reason
REST.DELETE.OBJECT	A	Not applicable	B	Yes	-	Cross-account access granted by bucket policy
REST.DELETE.OBJECT	A	Not applicable	B	No	Yes	Cross-account access relies on ACL
REST.PUT.ACL	*	*	*	Yes or No	Yes	Request grants ACL

Sample ACL

The following sample ACL on a bucket identifies the resource owner and a set of grants. The format is the XML representation of an ACL in the Amazon S3 REST API. The bucket owner has FULL_CONTROL of the resource. In addition, the ACL shows how permissions are granted on a resource to two AWS accounts, identified by canonical user ID, and two of the predefined Amazon S3 groups discussed in the preceding section.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<AccessControlPolicy xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Owner>
    <ID>Owner-canonical-user-ID</ID>
    <DisplayName>display-name</DisplayName>
  </Owner>
  <AccessControlList>
    <Grant>
```

```
<Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
  <ID>Owner-canonical-user-ID</ID>
  <DisplayName>display-name</DisplayName>
</Grantee>
<Permission>FULL_CONTROL</Permission>
</Grant>

<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
    <ID>user1-canonical-user-ID</ID>
    <DisplayName>display-name</DisplayName>
</Grantee>
<Permission>WRITE</Permission>
</Grant>

<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:type="CanonicalUser">
    <ID>user2-canonical-user-ID</ID>
    <DisplayName>display-name</DisplayName>
</Grantee>
<Permission>READ</Permission>
</Grant>

<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
</Grantee>
<Permission>READ</Permission>
</Grant>
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
</Grantee>
<Permission>WRITE</Permission>
</Grant>

</AccessControlList>
</AccessControlPolicy>
```

Canned ACL

Amazon S3 supports a set of predefined grants, known as *canned ACLs*. Each canned ACL has a predefined set of grantees and permissions. The following table lists the set of canned ACLs and the associated predefined grants.

Canned ACL	Applies to	Permissions added to ACL
private	Bucket and object	Owner gets FULL_CONTROL . No one else has access rights (default).
public-read	Bucket and object	Owner gets FULL_CONTROL . The AllUsers group (see Who is a grantee?) gets READ access.
public-read-write	Bucket and object	Owner gets FULL_CONTROL . The AllUsers group gets READ and WRITE access. Granting this on a bucket is generally not recommended.
aws-exec-read	Bucket and object	Owner gets FULL_CONTROL . Amazon EC2 gets READ access to GET an Amazon Machine Image (AMI) bundle from Amazon S3.
authenticated-read	Bucket and object	Owner gets FULL_CONTROL . The AuthenticatedUsers group gets READ access.
bucket-owner-read	Object	Object owner gets FULL_CONTROL . Bucket owner gets READ access. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.
bucket-owner-full-control	Object	Both the object owner and the bucket owner get FULL_CONTROL over the object. If you specify this canned ACL when creating a bucket, Amazon S3 ignores it.

Canned ACL	Applies to	Permissions added to ACL
log-delivery-write	Bucket	The LogDelivery group gets WRITE and READ_ACP permissions on the bucket. For more information about logs, see (Logging requests with server access logging).

Note

You can specify only one of these canned ACLs in your request.

You specify a canned ACL in your request by using the `x-amz-acl` request header. When Amazon S3 receives a request with a canned ACL in the request, it adds the predefined grants to the ACL of the resource.

Configuring ACLs

This section explains how to manage access permissions for S3 buckets and objects using access control lists (ACLs). You can add grants to your resource ACL using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs.

Bucket and object permissions are independent of each other. An object does not inherit the permissions from its bucket. For example, if you create a bucket and grant write access to a user, you can't access that user's objects unless the user explicitly grants you access.

You can grant permissions to other AWS account users or to predefined groups. The user or group that you are granting permissions to is called the *grantee*. By default, the owner, which is the AWS account that created the bucket, has full permissions.

Each permission you grant for a user or group adds an entry in the ACL that is associated with the bucket. The ACL lists grants, which identify the grantee and the permission granted.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled.

When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Warning

We highly recommend that you avoid granting write access to the **Everyone (public access)** or **Authenticated Users group (all AWS authenticated users)** groups. For more information about the effects of granting write access to these groups, see [Amazon S3 predefined groups](#).

Using the S3 console to set ACL permissions for a bucket

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs.

The following table shows the ACL permissions that you can configure for buckets in the Amazon S3 console.

Amazon S3 console ACL permissions for buckets

Console permission	ACL permission	Access
Objects - List	READ	Allows grantee to list the objects in the bucket.
Objects - Write	WRITE	Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.
Bucket ACL - Read	READ_ACP	Allows grantee to read the bucket ACL.
Bucket ACL - Write	WRITE_ACP	Allows grantee to write the ACL for the applicable bucket.
Everyone (public access): Objects - List	READ	Grants public read access for the objects in the bucket. When you grant list access to Everyone (public access) , anyone in the world can access the objects in the bucket.
Everyone (public access): Bucket ACL - Read	READ_ACP	Grants public read access for the bucket ACL. When you grant read access to Everyone (public access) , anyone in the world can access the bucket ACL.

For more information about ACL permissions, see [Access control list \(ACL\) overview](#).

⚠ Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLS) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set permissions for.
4. Choose **Permissions**.
5. Under **Access control list**, choose **Edit**.

You can edit the following ACL permissions for the bucket:

Objects

- **List** – Allows a grantee to list the objects in the bucket.
- **Write** – Allows grantee to create new objects in the bucket. For the bucket and object owners of existing objects, also allows deletions and overwrites of those objects.

In the S3 console, you can only grant write access to the S3 log delivery group and the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

Bucket ACL

- **Read** – Allows grantee to read the bucket ACL.
 - **Write** – Allows grantee to write the ACL for the applicable bucket.
6. To change the bucket owner's permissions, beside **Bucket owner (your AWS account)**, clear or select from the following ACL permissions:
 - **Objects – List or Write**
 - **Bucket ACL – Read or Write**

The *owner* refers to the AWS account root user, not an AWS Identity and Access Management IAM user. For more information about the root user, see [The AWS account root user](#) in the *IAM User Guide*.

7. To grant or undo permissions for the general public (everyone on the internet), beside **Everyone (public access)**, clear or select from the following ACL permissions:

- **Objects – List**
- **Bucket ACL – Read**

 **Warning**

Use caution when granting the **Everyone** group public access to your S3 bucket. When you grant access to this group, anyone in the world can access your bucket. We highly recommend that you never grant any kind of public write access to your S3 bucket.

8. To grant or undo permissions for anyone with an AWS account, beside **Authenticated Users group (anyone with an AWS account)**, clear or select from the following ACL permissions:

- **Objects – List**
- **Bucket ACL – Read**

9. To grant or undo permissions for Amazon S3 to write server access logs to the bucket, under **S3 log delivery group**, clear or select from the following ACL permissions:

- **Objects – List or Write**
- **Bucket ACL – Read or Write**

If a bucket is set up as the target bucket to receive access logs, the bucket permissions must allow the **Log Delivery** group write access to the bucket. When you enable server access logging on a bucket, the Amazon S3 console grants write access to the **Log Delivery** group for the target bucket that you choose to receive the logs. For more information about server access logging, see [Enabling Amazon S3 server access logging](#).

10. To grant access to another AWS account, do the following:

- a. Choose **Add grantee**.
- b. In the **Grantee** box, enter the canonical ID of the other AWS account.
- c. Select from the following ACL permissions:
 - **Objects – List or Write**
 - **Bucket ACL – Read or Write**

⚠️ Warning

When you grant other AWS accounts access to your resources, be aware that the AWS accounts can delegate their permissions to users under their accounts. This is known as *cross-account access*. For information about using cross-account access, see [Creating a Role to Delegate Permissions to an IAM User](#) in the *IAM User Guide*.

11. To remove access to another AWS account, under **Access for other AWS accounts**, choose **Remove**.
12. To save your changes, choose **Save changes**.

Using the S3 console to set ACL permissions for an object

The console displays combined access grants for duplicate grantees. To see the full list of ACLs, use the Amazon S3 REST API, AWS CLI, or AWS SDKs. The following table shows the ACL permissions that you can configure for objects in the Amazon S3 console.

Amazon S3 console ACL permissions for objects

Console permission	ACL permission	Access
Object - Read	READ	Allows grantee to read the object data and its metadata.
Object ACL - Read	READ_ACP	Allows grantee to read the object ACL.
Object ACL - Write	WRITE_ACP	Allows grantee to write the ACL for the applicable object

For more information about ACL permissions, see [Access control list \(ACL\) overview](#).

⚠️ Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and

return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To set ACL permissions for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **objects** list, choose the name of the object for which you want to set permissions.
4. Choose **Permissions**.
5. Under Access control list (ACL), choose **Edit**.

You can edit the following ACL permissions for the object:

Object

- **Read** – Allows grantee to read the object data and its metadata.

Object ACL

- **Read** – Allows grantee to read the object ACL.
- **Write** – Allows grantee to write the ACL for the applicable object. In the S3 console, you can only grant write access to the bucket owner (your AWS account). We highly recommend that you do not grant write access for other grantees. However, if you need to grant write access, you can use the AWS CLI, AWS SDKs, or the REST API.

6. You can manage object access permissions for the following:
 - a. **Access for object owner**

The *owner* refers to the AWS account root user, and not an AWS Identity and Access Management IAM user. For more information about the root user, see [The AWS account root user](#) in the *IAM User Guide*.

To change the owner's object access permissions, under **Access for object owner**, choose **Your AWS Account (owner)**.

Select the check boxes for the permissions that you want to change, and then choose **Save**.

b. **Access for other AWS accounts**

To grant permissions to an AWS user from a different AWS account, under **Access for other AWS accounts**, choose **Add account**. In the **Enter an ID** field, enter the canonical ID of the AWS user that you want to grant object permissions to. For information about finding a canonical ID, see [Your AWS account identifiers](#) in the *Amazon Web Services General Reference*. You can add as many as 99 users.

Select the check boxes for the permissions that you want to grant to the user, and then choose **Save**. To display information about the permissions, choose the Help icons.

c. **Public access**

To grant access to your object to the general public (everyone in the world), under **Public access**, choose **Everyone**. Granting public access permissions means that anyone in the world can access the object.

Select the check boxes for the permissions that you want to grant, and then choose **Save**.

 **Warning**

- Use caution when granting the **Everyone** group anonymous access to your Amazon S3 objects. When you grant access to this group, anyone in the world can access your object. If you need to grant access to everyone, we highly recommend that you only grant permissions to **Read objects**.
- We highly recommend that you *do not* grant the **Everyone** group write object permissions. Doing so allows anyone to overwrite the ACL permissions for the object.

Using the AWS SDKs

This section provides examples of how to configure access control list (ACL) grants on buckets and objects.

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Java

This section provides examples of how to configure access control list (ACL) grants on buckets and objects. The first example creates a bucket with a canned ACL (see [Canned ACL](#)), creates a list of custom permission grants, and then replaces the canned ACL with an ACL containing the custom grants. The second example shows how to modify an ACL using the `AccessControlList.grantPermission()` method.

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This example creates a bucket. In the request, the example specifies a canned ACL that grants the Log Delivery group permission to write logs to the bucket.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.ArrayList;

public class CreateBucketWithACL {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String userEmailForReadPermission = "*** user@example.com ***";
```

```
try {
    AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
        .withRegion(clientRegion)
        .build();

    // Create a bucket with a canned ACL. This ACL will be replaced by the
    // setBucketAcl()
    // calls below. It is included here for demonstration purposes.
    CreateBucketRequest createBucketRequest = new
CreateBucketRequest(bucketName, clientRegion.getName())
    .withCannedAcl(CannedAccessControlList.LogDeliveryWrite);
    s3Client.createBucket(createBucketRequest);

    // Create a collection of grants to add to the bucket.
    ArrayList<Grant> grantCollection = new ArrayList<Grant>();

    // Grant the account owner full control.
    Grant grant1 = new Grant(new
CanonicalGrantee(s3Client.getS3AccountOwner().getId()),
        Permission.FullControl);
    grantCollection.add(grant1);

    // Grant the LogDelivery group permission to write to the bucket.
    Grant grant2 = new Grant(GroupGrantee.LogDelivery, Permission.Write);
    grantCollection.add(grant2);

    // Save grants by replacing all current ACL grants with the two we just
created.
    AccessControlList bucketAcl = new AccessControlList();
    bucketAcl.grantAllPermissions(grantCollection.toArray(new Grant[0]));
    s3Client.setBucketAcl(bucketName, bucketAcl);

    // Retrieve the bucket's ACL, add another grant, and then save the new
ACL.
    AccessControlList newBucketAcl = s3Client.getBucketAcl(bucketName);
    Grant grant3 = new Grant(new
EmailAddressGrantee(userEmailForReadPermission), Permission.Read);
    newBucketAcl.grantAllPermissions(grant3);
    s3Client.setBucketAcl(bucketName, newBucketAcl);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
```

```
// Amazon S3 couldn't be contacted for a response, or the client  
// couldn't parse the response from Amazon S3.  
e.printStackTrace();  
}  
}  
}
```

Example Update ACL on an existing object

This example updates the ACL on an object. The example performs the following tasks:

- Retrieves an object's ACL
- Clears the ACL by removing all existing permissions
- Adds two permissions: full access to the owner, and WRITE_ACP (see [What permissions can I grant?](#)) to a user identified by an email address
- Saves the ACL to the object

```
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.regions.Regions;  
import com.amazonaws.services.s3.AmazonS3;  
import com.amazonaws.services.s3.AmazonS3ClientBuilder;  
import com.amazonaws.services.s3.model.AccessControlList;  
import com.amazonaws.services.s3.model.CanonicalGrantee;  
import com.amazonaws.services.s3.model.EmailAddressGrantee;  
import com.amazonaws.services.s3.model.Permission;  
  
import java.io.IOException;  
  
public class ModifyACLExistingObject {  
  
    public static void main(String[] args) throws IOException {  
        Regions clientRegion = Regions.DEFAULT_REGION;  
        String bucketName = "**** Bucket name ****";  
        String keyName = "**** Key name ****";  
        String emailGrantee = "**** user@example.com ****";  
  
        try {
```

```
AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(clientRegion)
    .build();

    // Get the existing object ACL that we want to modify.
    AccessControlList acl = s3Client.getObjectAcl(bucketName, keyName);

    // Clear the existing list of grants.
    acl.getGrantsAsList().clear();

    // Grant a sample set of permissions, using the existing ACL owner for
Full
    // Control permissions.
    acl.grantPermission(new CanonicalGrantee(acl.getOwner().getId()),
Permission.FullControl);
    acl.grantPermission(new EmailAddressGrantee(emailGrantee),
Permission.WriteAcp);

    // Save the modified ACL back to the object.
    s3Client.setObjectAcl(bucketName, keyName, acl);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

.NET

Example Create a bucket and specify a canned ACL that grants permission to the S3 log delivery group

This C# example creates a bucket. In the request, the code also specifies a canned ACL that grants the Log Delivery group permissions to write the logs to the bucket.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingBucketACLTest
    {
        private const string newBucketName = "*** bucket name ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            CreateBucketUseCannedACLAsync().Wait();
        }

        private static async Task CreateBucketUseCannedACLAsync()
        {
            try
            {
                // Add bucket (specify canned ACL).
                PutBucketRequest putBucketRequest = new PutBucketRequest()
                {
                    BucketName = newBucketName,
                    BucketRegion = S3Region.EUW1, // S3Region.US,
                                            // Add canned ACL.
                    CannedACL = S3CannedACL.LogDeliveryWrite
                };
                PutBucketResponse putBucketResponse = await
client.PutBucketAsync(putBucketRequest);

                // Retrieve bucket ACL.
                GetACLResponse getACLResponse = await client.GetACLAsync(new
GetACLRequest
                {
                    BucketName = newBucketName
                });
            }
        }
    }
}
```

```
        }
        catch (AmazonS3Exception amazonS3Exception)
        {
            Console.WriteLine("S3 error occurred. Exception: " +
amazonS3Exception.ToString());
        }
        catch (Exception e)
        {
            Console.WriteLine("Exception: " + e.ToString());
        }
    }
}
```

Example Update ACL on an existing object

This C# example updates the ACL on an existing object. The example performs the following tasks:

- Retrieves an object's ACL.
- Clears the ACL by removing all existing permissions.
- Adds two permissions: full access to the owner, and WRITE_ACP to a user identified by email address.
- Saves the ACL by sending a PutAcl request.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class ManagingObjectACLTTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** object key name ***";
```

```
private const string emailAddress = "*** email address ***";
// Specify your bucket region (an example region is shown).
private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
private static IAmazonS3 client;
public static void Main()
{
    client = new AmazonS3Client(bucketRegion);
    TestObjectACLTestAsync().Wait();
}
private static async Task TestObjectACLTestAsync()
{
    try
    {
        // Retrieve the ACL for the object.
        GetACLResponse aclResponse = await client.GetACLAsync(new
GetACLRequest
{
    BucketName = bucketName,
    Key = keyName
});

        S3AccessControlList acl = aclResponse.AccessControlList;

        // Retrieve the owner (we use this to re-add permissions after
we clear the ACL).
        Owner owner = acl.Owner;

        // Clear existing grants.
        acl.Grants.Clear();

        // Add a grant to reset the owner's full permission (the
previous clear statement removed all permissions).
        S3Grant fullControlGrant = new S3Grant
{
    Grantee = new S3Grantee { CanonicalUser = owner.Id },
    Permission = S3Permission.FULL_CONTROL
};

        // Describe the grant for the permission using an email address.
        S3Grant grantUsingEmail = new S3Grant
{
    Grantee = new S3Grantee { EmailAddress = emailAddress },
}
```

```
        Permission = S3Permission.WRITE_ACP
    };
    acl.Grants.AddRange(new List<S3Grant> { fullControlGrant,
grantUsingEmail });

        // Set a new ACL.
PutACLResponse response = await client.PutACLAsync(new
PutACLRequest
{
    BucketName = bucketName,
    Key = keyName,
    AccessControlList = acl
});
}
catch (AmazonS3Exception amazonS3Exception)
{
    Console.WriteLine("An AmazonS3Exception was thrown. Exception: " +
amazonS3Exception.ToString());
}
catch (Exception e)
{
    Console.WriteLine("Exception: " + e.ToString());
}
}
}
}
```

Using the REST API

Amazon S3 APIs enable you to set an ACL when you create a bucket or an object. Amazon S3 also provides API to set an ACL on an existing bucket or an object. These APIs provide the following methods to set an ACL:

- **Set ACL using request headers**— When you send a request to create a resource (bucket or object), you set an ACL using the request headers. Using these headers, you can either specify a canned ACL or specify grants explicitly (identifying grantee and permissions explicitly).
- **Set ACL using request body**— When you send a request to set an ACL on an existing resource, you can set the ACL either in the request header or in the body.

For information on the REST API support for managing ACLs, see the following sections in the *Amazon Simple Storage Service API Reference*:

- [GET Bucket acl](#)
- [PUT Bucket acl](#)
- [GET Object acl](#)
- [PUT Object acl](#)
- [PUT Object](#)
- [PUT Bucket](#)
- [PUT Object - Copy](#)
- [Initiate Multipart Upload](#)

 **Important**

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the AccessControlListNotSupported error code. Requests to read ACLs are still supported.

Access Control List (ACL)-Specific Request Headers

You can use headers to grant access control list (ACL)-based permissions. By default, all objects are private. Only the owner has full access control. When adding a new object, you can grant permissions to individual AWS accounts or to predefined groups defined by Amazon S3. These permissions are then added to the Access Control List (ACL) on the object. For more information, see [Access control list \(ACL\) overview](#).

With this operation, you can grant access permissions using one of these two methods:

- **Canned ACL (`x-amz-acl`)** — Amazon S3 supports a set of predefined ACLs, known as canned ACLs. Each canned ACL has a predefined set of grantees and permissions. For more information, see [Canned ACL](#).
- **Access Permissions** — To explicitly grant access permissions to specific AWS accounts or groups, use the following headers. Each header maps to specific permissions that Amazon S3 supports in

an ACL. For more information, see [Access control list \(ACL\) overview](#). In the header, you specify a list of grantees who get the specific permission.

- x-amz-grant-read
- x-amz-grant-write
- x-amz-grant-read-acp
- x-amz-grant-write-acp
- x-amz-grant-full-control

Using the AWS CLI

For more information about managing ACLs using the AWS CLI, see [put-bucket-acl](#) in the *AWS CLI Command Reference*.

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

Policy examples for ACLs

You can use condition keys in bucket policies to control access to Amazon S3.

Topics

- [Granting s3:PutObject permission with a condition requiring the bucket owner to get full control](#)
- [Granting s3:PutObject permission with a condition on the x-amz-acl header](#)

Granting s3:PutObject permission with a condition requiring the bucket owner to get full control

The [PUT Object](#) operation allows access control list (ACL)-specific headers that you can use to grant ACL-based permissions. Using these keys, the bucket owner can set a condition to require specific access permissions when the user uploads an object.

Suppose that Account A owns a bucket, and the account administrator wants to grant Dave, a user in Account B, permissions to upload objects. By default, objects that Dave uploads are owned by Account B, and Account A has no permissions on these objects. Because the bucket owner is paying the bills, it wants full permissions on the objects that Dave uploads. The Account A administrator can do this by granting the `s3:PutObject` permission to Dave, with a condition that the request include ACL-specific headers that either grant full permission explicitly or use a canned ACL. For more information, see [PUT Object](#).

Require the `x-amz-full-control` header

You can require the `x-amz-full-control` header in the request with full control permission to the bucket owner. The following bucket policy grants the `s3:PutObject` permission to user Dave with a condition using the `s3:x-amz-grant-full-control` condition key, which requires the request to include the `x-amz-full-control` header.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "statement1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::AccountB-ID:user/Dave"  
            },  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"  
                }  
            }  
        }  
    ]  
}
```

Note

This example is about cross-account permission. However, if Dave (who is getting the permission) belongs to the AWS account that owns the bucket, this conditional permission

is not necessary. This is because the parent account to which Dave belongs owns objects that the user uploads.

Add explicit deny

The preceding bucket policy grants conditional permission to user Dave in Account B. While this policy is in effect, it is possible for Dave to get the same permission without any condition via some other policy. For example, Dave can belong to a group, and you grant the group s3:PutObject permission without any condition. To avoid such permission loopholes, you can write a stricter access policy by adding explicit deny. In this example, you explicitly deny the user Dave upload permission if he does not include the necessary headers in the request granting full permissions to the bucket owner. Explicit deny always supersedes any other permission granted. The following is the revised access policy example with explicit deny added.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"
                }
            }
        },
        {
            "Sid": "statement2",
            "Effect": "Deny",
            "Principal": {
                "AWS": "arn:aws:iam::AccountB-ID:user/AccountBadmin"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::awsexamplebucket1/*",
            "Condition": {
                "StringNotEquals": {
```

```
        "s3:x-amz-grant-full-control": "id=AccountA-CanonicalUserID"  
    }  
}  
}  
]  
}
```

Test the policy with the AWS CLI

If you have two AWS accounts, you can test the policy using the AWS Command Line Interface (AWS CLI). You attach the policy and use Dave's credentials to test the permission using the following AWS CLI put-object command. You provide Dave's credentials by adding the --profile parameter. You grant full control permission to the bucket owner by adding the --grant-full-control parameter. For more information about setting up and using the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg  
--grant-full-control id="AccountA-CanonicalUserID" --profile AccountBUserProfile
```

Require the x-amz-acl header

You can require the x-amz-acl header with a canned ACL granting full control permission to the bucket owner. To require the x-amz-acl header in the request, you can replace the key-value pair in the Condition block and specify the s3:x-amz-acl condition key, as shown in the following example.

```
"Condition": {  
    "StringEquals": {  
        "s3:x-amz-acl": "bucket-owner-full-control"  
    }  
}
```

To test the permission using the AWS CLI, you specify the --acl parameter. The AWS CLI then adds the x-amz-acl header when it sends the request.

```
aws s3api put-object --bucket examplebucket --key HappyFace.jpg --body c:\HappyFace.jpg  
--acl "bucket-owner-full-control" --profile AccountBadmin
```

Granting s3:PutObject permission with a condition on the x-amz-acl header

The following bucket policy grants the s3:PutObject permission for two AWS accounts if the request includes the x-amz-acl header making the object publicly readable. The Condition block uses the StringEquals condition, and it is provided a key-value pair, "s3:x-amz-acl": ["public-read"], for evaluation. In the key-value pair, the s3:x-amz-acl is an Amazon S3-specific key, as indicated by the prefix s3:::

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AddCannedAcl",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::Account1-ID:root",  
                    "arn:aws:iam::Account2-ID:root"  
                ]  
            },  
            "Action": "s3:PutObject",  
            "Resource": ["arn:aws:s3:::awsexamplebucket1/*"],  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": ["public-read"]  
                }  
            }  
        }  
    ]  
}
```

Important

Not all conditions make sense for all actions. For example, it makes sense to include an s3:LocationConstraint condition on a policy that grants the s3>CreateBucket Amazon S3 permission. However, it does not make sense to include this condition on a policy that grants the s3:GetObject permission. Amazon S3 can test for semantic errors of this type that involve Amazon S3-specific conditions. However, if you are creating a policy for an IAM user or role and you include a semantically invalid Amazon S3 condition, no error is reported because IAM cannot validate Amazon S3 conditions.

Blocking public access to your Amazon S3 storage

The Amazon S3 Block Public Access feature provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects don't allow public access. However, users can modify bucket policies, access point policies, or object permissions to allow public access. S3 Block Public Access settings override these policies and permissions so that you can limit public access to these resources.

With S3 Block Public Access, account administrators and bucket owners can easily set up centralized controls to limit public access to their Amazon S3 resources that are enforced regardless of how the resources are created.

For instructions on configuring public block access, see [Configuring block public access](#).

When Amazon S3 receives a request to access a bucket or an object, it determines whether the bucket or the bucket owner's account has a block public access setting applied. If the request was made through an access point, Amazon S3 also checks for block public access settings for the access point. If there is an existing block public access setting that prohibits the requested access, Amazon S3 rejects the request.

Amazon S3 Block Public Access provides four settings. These settings are independent and can be used in any combination. Each setting can be applied to an access point, a bucket, or an entire AWS account. If the block public access settings for the access point, bucket, or account differ, then Amazon S3 applies the most restrictive combination of the access point, bucket, and account settings.

When Amazon S3 evaluates whether an operation is prohibited by a block public access setting, it rejects any request that violates an access point, bucket, or account setting.

Important

Public access is granted to buckets and objects through access control lists (ACLs), access point policies, bucket policies, or all. To help ensure that all of your Amazon S3 access points, buckets, and objects have their public access blocked, we recommend that you turn on all four settings for block public access for your account. These settings block public access for all current and future buckets and access points.

Before applying these settings, verify that your applications will work correctly without public access. If you require some level of public access to your buckets or objects, for

example to host a static website as described at [Hosting a static website using Amazon S3](#), you can customize the individual settings to suit your storage use cases. Enabling Block Public Access helps protect your resources by preventing public access from being granted through the resource policies or access control lists (ACLs) that are directly attached to S3 resources. In addition to enabling Block Public Access, carefully inspect the following policies to confirm that they don't grant public access:

- Identity-based policies attached to associated AWS principals (for example, IAM roles)
- Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

Note

- You can enable block public access settings only for access points, buckets, and AWS accounts. Amazon S3 doesn't support block public access settings on a per-object basis.
- When you apply block public access settings to an account, the settings apply to all AWS Regions globally. The settings might not take effect in all Regions immediately or simultaneously, but they eventually propagate to all Regions.

Topics

- [Block public access settings](#)
- [Performing block public access operations on an access point](#)
- [The meaning of "public"](#)
- [Using IAM Access Analyzer for S3 to review public buckets](#)

- [Configuring block public access settings for your account](#)
- [Configuring block public access settings for your S3 buckets](#)

Block public access settings

S3 Block Public Access provides four settings. You can apply these settings in any combination to individual access points, buckets, or entire AWS accounts. If you apply a setting to an account, it applies to all buckets and access points that are owned by that account. Similarly, if you apply a setting to a bucket, it applies to all access points associated with that bucket.

The following table contains the available settings.

Name	Description
BlockPublicAcls	<p>Setting this option to TRUE causes the following behavior:</p> <ul style="list-style-type: none">• PutBucketAcl and PutObjectAcl calls fail if the specified access control list (ACL) is public.• PutObject calls fail if the request includes a public ACL.• If this setting is applied to an account, then PUT Bucket calls fail if the request includes a public ACL. <p>When this setting is set to TRUE, the specified operations fail (whether made through the REST API, AWS CLI, or AWS SDKs). However, existing policies and ACLs for buckets and objects aren't modified. This setting enables you to protect against public access while allowing you to audit, refine, or otherwise alter the existing policies and ACLs for your buckets and objects.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p> Note</p><p>Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.</p></div>

Name	Description
IgnorePublicAccls	Setting this option to TRUE causes Amazon S3 to ignore all public ACLs on a bucket and any objects that it contains. This setting enables you to safely block public access granted by ACLs while still allowing PutObject calls that include a public ACL (as opposed to BlockPublicAccls, which rejects PutObject calls that include a public ACL). Enabling this setting doesn't affect the persistence of any existing ACLs and doesn't prevent new public ACLs from being set.

 **Note**

Access points don't have ACLs associated with them. If you apply this setting to an access point, it acts as a passthrough to the underlying bucket. If an access point has this setting enabled, requests made through the access point behave as though the underlying bucket has this setting enabled, regardless of whether the bucket actually has this setting enabled.

Name	Description
BlockPublicPolicy	<p>Setting this option to TRUE for a bucket causes Amazon S3 to reject calls to <code>PutBucketPolicy</code> if the specified bucket policy allows public access. Setting this option to TRUE for a bucket also causes Amazon S3 to reject calls to <code>PutAccessPointPolicy</code> for all of the bucket's same-account access points if the specified policy allows public access.</p> <p>Setting this option to TRUE for an access point causes Amazon S3 to reject calls to <code>PutAccessPointPolicy</code> and <code>PutBucketPolicy</code> that are made through the access point if the specified policy (for either the access point or the underlying bucket) allows public access.</p> <p>You can use this setting to allow users to manage access point and bucket policies without allowing them to publicly share the bucket or the object it contains. Enabling this setting doesn't affect existing access point or bucket policies.</p>

 **Important**

To use this setting effectively, we recommend that you apply it at the *account* level. A bucket policy can allow users to alter a bucket's block public access settings. Therefore, users who have permission to change a bucket policy could insert a policy that allows them to disable the block public access settings for the bucket. If this setting is enabled for the entire account, rather than for a specific bucket, Amazon S3 blocks public policies even if a user alters the bucket policy to disable this setting.

Name	Description
RestrictPublicBuckets	<p>Setting this option to TRUE restricts access to an access point or bucket with a public policy to only AWS service principals and authorized users within the bucket owner's account and access point owner's account. This setting blocks all cross-account access to the access point or bucket (except by AWS service principals), while still allowing users within the account to manage the access point or bucket.</p> <p>Enabling this setting doesn't affect existing access point or bucket policies, except that Amazon S3 blocks public and cross-account access derived from any public access point or bucket policy, including non-public delegation to specific accounts.</p>

Important

- Calls to `GetBucketAcl` and `GetObjectAcl` always return the effective permissions in place for the specified bucket or object. For example, suppose that a bucket has an ACL that grants public access, but the bucket also has the `IgnorePublicAccls` setting enabled. In this case, `GetBucketAcl` returns an ACL that reflects the access permissions that Amazon S3 is enforcing, rather than the actual ACL that is associated with the bucket.
- Block public access settings don't alter existing policies or ACLs. Therefore, removing a block public access setting causes a bucket or object with a public policy or ACL to again be publicly accessible.

Performing block public access operations on an access point

To perform block public access operations on an access point, use the AWS CLI service `s3control`.

⚠ Important

You can't change an access point's block public access settings after creating the access point. You can specify block public access settings for an access point only when creating the access point.

The meaning of "public"

ACLs

Amazon S3 considers a bucket or object ACL public if it grants any permissions to members of the predefined `AllUsers` or `AuthenticatedUsers` groups. For more information about predefined groups, see [Amazon S3 predefined groups](#).

Bucket policies

When evaluating a bucket policy, Amazon S3 begins by assuming that the policy is public. It then evaluates the policy to determine whether it qualifies as non-public. To be considered non-public, a bucket policy must grant access only to fixed values (values that don't contain a wildcard or [an AWS Identity and Access Management Policy Variable](#)) for one or more of the following:

- An AWS principal, user, role, or service principal (e.g. `aws:PrincipalOrgID`)
- A set of Classless Inter-Domain Routings (CIDR) blocks, using `aws:SourceIp`. For more information about CIDR, see [RFC 4632](#) on the RFC Editor website.

ⓘ Note

Bucket policies that grant access conditioned on the `aws:SourceIp` condition key with very broad IP ranges (for example, `0.0.0.0/1`) are evaluated as "public." This includes values broader than `/8` for IPv4 and `/32` for IPv6 (excluding RFC1918 private ranges). Block public access will reject these "public" policies and prevent cross-account access to buckets that are already using these "public" policies.

- `aws:SourceArn`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:SourceOwner`

- aws:SourceAccount
- aws:userid, outside the pattern "AROLEID:/*"
- s3:DataAccessPointArn

 **Note**

When used in a bucket policy, this value can contain a wildcard for the access point name without rendering the policy public, as long as the account ID is fixed. For example, allowing access to arn:aws:s3:us-west-2:123456789012:accesspoint/* would permit access to any access point associated with account 123456789012 in Region us-west-2, without rendering the bucket policy public. This behavior is different for access point policies. For more information, see [Access points](#).

- s3:DataAccessPointAccount

For more information about bucket policies, see [Bucket policies for Amazon S3](#).

 **Note**

When using [multivalued context keys](#), you must use the ForAllValues or ForAnyValue set operators.

Example : Public bucket policies

Under these rules, the following example policies are considered public.

```
{  
    "Principal": "*",
    "Resource": "*",
    "Action": "s3:PutObject",
    "Effect": "Allow"
}
```

```
{  
    "Principal": "*",
    "Resource": "*",
    "Action": "s3:PutObject",
    "Effect": "Allow",
}
```

```
"Condition": { "StringLike": {"aws:SourceVpc": "vpc-*"}}  
}
```

You can make these policies non-public by including any of the condition keys listed previously, using a fixed value. For example, you can make the last policy preceding non-public by setting `aws:SourceVpc` to a fixed value, like the following.

```
{  
    "Principal": "*",  
    "Resource": "*",  
    "Action": "s3:PutObject",  
    "Effect": "Allow",  
    "Condition": {"StringEquals": {"aws:SourceVpc": "vpc-91237329"}}  
}
```

How Amazon S3 evaluates a bucket policy that contains both public and non-public access grants

This example shows how Amazon S3 evaluates a bucket policy that contains both public and non-public access grants.

Suppose that a bucket has a policy that grants access to a set of fixed principals. Under the previously described rules, this policy isn't public. Thus, if you enable the `RestrictPublicBuckets` setting, the policy remains in effect as written, because `RestrictPublicBuckets` only applies to buckets that have public policies. However, if you add a public statement to the policy, `RestrictPublicBuckets` takes effect on the bucket. It allows only AWS service principals and authorized users of the bucket owner's account to access the bucket.

As an example, suppose that a bucket owned by "Account-1" has a policy that contains the following:

1. A statement that grants access to AWS CloudTrail (which is an AWS service principal)
2. A statement that grants access to account "Account-2"
3. A statement that grants access to the public, for example by specifying "Principal": "*" with no limiting Condition

This policy qualifies as public because of the third statement. With this policy in place and `RestrictPublicBuckets` enabled, Amazon S3 allows access only by CloudTrail. Even though

statement 2 isn't public, Amazon S3 disables access by "Account-2." This is because statement 3 renders the entire policy public, so `RestrictPublicBuckets` applies. As a result, Amazon S3 disables cross-account access, even though the policy delegates access to a specific account, "Account-2." But if you remove statement 3 from the policy, then the policy doesn't qualify as public, and `RestrictPublicBuckets` no longer applies. Thus, "Account-2" regains access to the bucket, even if you leave `RestrictPublicBuckets` enabled.

Access points

Amazon S3 evaluates block public access settings slightly differently for access points compared to buckets. The rules that Amazon S3 applies to determine when an access point policy is public are generally the same for access points as for buckets, except in the following situations:

- An access point that has a VPC network origin is always considered non-public, regardless of the contents of its access point policy.
- An access point policy that grants access to a set of access points using `s3:DataAccessPointArn` is considered public. Note that this behavior is different than for bucket policies. For example, a bucket policy that grants access to values of `s3:DataAccessPointArn` that match `arn:aws:s3:us-west-2:123456789012:accesspoint/*` is not considered public. However, the same statement in an access point policy would render the access point public.

Using IAM Access Analyzer for S3 to review public buckets

You can use IAM Access Analyzer for S3 to review buckets with bucket ACLs, bucket policies, or access point policies that grant public access. IAM Access Analyzer for S3 alerts you to buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings that report the source and level of public or shared access.

In IAM Access Analyzer for S3, you can block all public access to a bucket with a single click. You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public or shared access, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket.

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose

that the bucket policy contains an Action statement that allows public access for an action that isn't supported by Amazon S3 (for example, s3:NotASupportedAction). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

For more information about IAM Access Analyzer for S3, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Permissions

To use Amazon S3 Block Public Access features, you must have the following permissions.

Operation	Required permissions
GET bucket policy status	s3:GetBucketPolicyStatus
GET bucket Block Public Access settings	s3:GetBucketPublicAccessBlock
PUT bucket Block Public Access settings	s3:PutBucketPublicAccessBlock
DELETE bucket Block Public Access settings	s3:PutBucketPublicAccessBlock
GET account Block Public Access settings	s3:GetAccountPublicAccessBlock
PUT account Block Public Access settings	s3:PutAccountPublicAccessBlock
DELETE account Block Public Access settings	s3:PutAccountPublicAccessBlock
PUT access point Block Public Access settings	s3>CreateAccessPoint

 **Note**

The DELETE operations require the same permissions as the PUT operations. There are no separate permissions for the DELETE operations.

Configuring block public access

For more information about configuring block public access for your AWS account, your Amazon S3 buckets, and your access points, see the following topics:

- [Configuring block public access settings for your account](#)
- [Configuring block public access settings for your S3 buckets](#)
- [Performing block public access operations on an access point](#)

Configuring block public access settings for your account

Amazon S3 Block Public Access provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access.

For more information, see [Blocking public access to your Amazon S3 storage](#).

Note

Account level settings override settings on individual objects. Configuring your account to block public access will override any public access settings made to individual objects within your account.

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to configure block public access settings for all the buckets in your account. For more information, see the sections below.

To configure block public access settings for your buckets, see [Configuring block public access settings for your S3 buckets](#). For information about access points, see [Performing block public access operations on an access point](#).

Using the S3 console

Amazon S3 block public access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit block public access settings for all the S3 buckets in your AWS account. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

To edit block public access settings for all the S3 buckets in an AWS account

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Block Public Access settings for this account**.
3. Choose **Edit** to change the block public access settings for all the buckets in your AWS account.
4. Choose the settings that you want to change, and then choose **Save changes**.
5. When you're asked for confirmation, enter **confirm**. Then choose **Confirm** to save your changes.

Using the AWS CLI

You can use Amazon S3 Block Public Access through the AWS CLI. For more information about setting up and using the AWS CLI, see [What is the AWS Command Line Interface?](#)

Account

To perform block public access operations on an account, use the AWS CLI service `s3control`.

The account-level operations that use this service are as follows:

- `PutPublicAccessBlock` (for an account)
- `GetPublicAccessBlock` (for an account)
- `DeletePublicAccessBlock` (for an account)

For additional information and examples, see [put-public-access-block](#) in the *AWS CLI Reference*.

Using the AWS SDKs

Java

The following examples show you how to use Amazon S3 Block Public Access with the AWS SDK for Java to put a public access block configuration on an Amazon S3 account.

```
AWSS3ControlClientBuilder controlClientBuilder =
    AWSS3ControlClientBuilder.standard();
controlClientBuilder.setRegion(<region>);
controlClientBuilder.setCredentials(<credentials>);
```

```
AWSS3Control client = controlClientBuilder.build();
client.putPublicAccessBlock(new PutPublicAccessBlockRequest()
    .withAccountId(<account-id>)
    .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
        .withIgnorePublicAcls(<value>)
        .withBlockPublicAcls(<value>)
        .withBlockPublicPolicy(<value>)
        .withRestrictPublicBuckets(<value>))));
```

Important

This example pertains only to account-level operations, which use the `AWSS3Control` client class. For bucket-level operations, see the preceding example.

Other SDKs

For information about using the other AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Account-level operations
 - [PutPublicAccessBlock](#)
 - [GetPublicAccessBlock](#)
 - [DeletePublicAccessBlock](#)

Configuring block public access settings for your S3 buckets

Amazon S3 Block Public Access provides settings for access points, buckets, and accounts to help you manage public access to Amazon S3 resources. By default, new buckets, access points, and objects do not allow public access.

For more information, see [Blocking public access to your Amazon S3 storage](#).

You can use the S3 console, AWS CLI, AWS SDKs, and REST API to grant public access to one or more buckets. You can also block public access to buckets that are already public. For more information, see the sections below.

To configure block public access settings for every bucket in your account, see [Configuring block public access settings for your account](#). For information about configuring block public access for access points, see [Performing block public access operations on an access point](#).

Using the S3 console

Amazon S3 Block Public Access prevents the application of any settings that allow public access to data within S3 buckets. This section describes how to edit Block Public Access settings for one or more S3 buckets. For information about blocking public access using the AWS CLI, AWS SDKs, and the Amazon S3 REST APIs, see [Blocking public access to your Amazon S3 storage](#).

You can see if your bucket is publicly accessible in the **Buckets** list. In the **Access** column, Amazon S3 labels the permissions for a bucket as follows:

- **Public** – Everyone has access to one or more of the following: List objects, Write objects, Read and write permissions.
- **Objects can be public** – The bucket is not public, but anyone with the appropriate permissions can grant public access to objects.
- **Buckets and objects not public** – The bucket and objects do not have any public access.
- **Only authorized users of this account** – Access is isolated to IAM users and roles in this account and AWS service principals because there is a policy that grants public access.

You can also filter bucket searches by access type. Choose an access type from the drop-down list that is next to the **Search for buckets** bar.

If you see an **Error** when you list your buckets and their public access settings, you might not have the required permissions. Check to make sure you have the following permissions added to your user or role policy:

```
s3:GetAccountPublicAccessBlock  
s3:GetBucketPublicAccessBlock  
s3:GetBucketPolicyStatus  
s3:GetBucketLocation  
s3:GetBucketAcl  
s3>ListAccessPoints
```

s3>ListAllMyBuckets

In some rare cases, requests can also fail because of an AWS Region outage.

To edit the Amazon S3 block public access settings for a single S3 bucket

Follow these steps if you need to change the public access settings for a single S3 bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Bucket name** list, choose the name of the bucket that you want.
3. Choose **Permissions**.
4. Choose **Edit** to change the public access settings for the bucket. For more information about the four Amazon S3 Block Public Access Settings, see [Block public access settings](#).
5. Choose the setting that you want to change, and then choose **Save**.
6. When you're asked for confirmation, enter **confirm**. Then choose **Confirm** to save your changes.

You can change Amazon S3 Block Public Access settings when you create a bucket. For more information, see [Creating a bucket](#).

Using the AWS CLI

To block public access on a bucket or to delete the public access block, use the AWS CLI service `s3api`. The bucket-level operations that use this service are as follows:

- `PutPublicAccessBlock` (for a bucket)
- `GetPublicAccessBlock` (for a bucket)
- `DeletePublicAccessBlock` (for a bucket)
- `GetBucketPolicyStatus`

For more information and examples, see [put-public-access-block](#) in the *AWS CLI Reference*.

Using the AWS SDKs

Java

```
AmazonS3 client = AmazonS3ClientBuilder.standard()
    .withCredentials(<credentials>)
    .build();

client.setPublicAccessBlock(new SetPublicAccessBlockRequest()
    .withBucketName(<bucket-name>)
    .withPublicAccessBlockConfiguration(new PublicAccessBlockConfiguration()
        .withBlockPublicAcls(<value>)
        .withIgnorePublicAcls(<value>)
        .withBlockPublicPolicy(<value>)
        .withRestrictPublicBuckets(<value>)));

```

Important

This example pertains only to bucket-level operations, which use the AmazonS3 client class. For account-level operations, see the following example.

Other SDKs

For information about using the other AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Using the REST API

For information about using Amazon S3 Block Public Access through the REST APIs, see the following topics in the *Amazon Simple Storage Service API Reference*.

- Bucket-level operations
 - [PutPublicAccessBlock](#)
 - [GetPublicAccessBlock](#)
 - [DeletePublicAccessBlock](#)
 - [GetBucketPolicyStatus](#)

Reviewing bucket access using IAM Access Analyzer for S3

IAM Access Analyzer for S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including AWS accounts outside of your organization. For each public or shared bucket, you receive findings into the source and level of public or shared access. For example, IAM Access Analyzer for S3 might show that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. With these findings, you can take immediate and precise corrective action to restore your bucket access to what you intended.

When reviewing an at-risk bucket in IAM Access Analyzer for S3, you can block all public access to the bucket with a single click. We recommend that you block all access to your buckets unless you require public access to support a specific use case. Before you block all public access, ensure that your applications will continue to work correctly without public access. For more information, see [Blocking public access to your Amazon S3 storage](#).

You can also drill down into bucket-level permission settings to configure granular levels of access. For specific and verified use cases that require public access, such as static website hosting, public downloads, or cross-account sharing, you can acknowledge and record your intent for the bucket to remain public or shared by archiving the findings for the bucket. You can revisit and modify these bucket configurations at any time. You can also download your findings as a CSV report for auditing purposes.

IAM Access Analyzer for S3 is available at no extra cost on the Amazon S3 console. IAM Access Analyzer for S3 is powered by AWS Identity and Access Management (IAM) IAM Access Analyzer. To use IAM Access Analyzer for S3 in the Amazon S3 console, you must visit the IAM console and enable IAM Access Analyzer on a per-Region basis.

For more information about IAM Access Analyzer, see [What is IAM Access Analyzer?](#) in the *IAM User Guide*. For more information about IAM Access Analyzer for S3, review the following sections.

Important

- IAM Access Analyzer for S3 requires an account-level analyzer. To use IAM Access Analyzer for S3, you must visit IAM Access Analyzer and create an analyzer that has an account as the zone of trust. For more information, see [Enabling IAM Access Analyzer](#) in *IAM User Guide*.

- IAM Access Analyzer for S3 doesn't analyze the access point policy that's attached to cross-account access points. This behavior occurs because the access point and its policy are outside the zone of trust, that is, the account. Buckets that delegate access to a cross-account access point are listed under **Buckets with public access** if you haven't applied the `RestrictPublicBuckets` block public access setting to the bucket or account. When you apply the `RestrictPublicBuckets` block public access setting, the bucket is reported under **Buckets with access from other AWS accounts — including third-party AWS accounts**.
- When a bucket policy or bucket ACL is added or modified, IAM Access Analyzer generates and updates findings based on the change within 30 minutes. Findings related to account level block public access settings might not be generated or updated for up to 6 hours after you change the settings. Findings related to Multi-Region Access Points might not be generated or updated for up to six hours after the Multi-Region Access Point is created, deleted, or you change its policy.

Topics

- [What information does IAM Access Analyzer for S3 provide?](#)
- [Enabling IAM Access Analyzer for S3](#)
- [Blocking all public access](#)
- [Reviewing and changing bucket access](#)
- [Archiving bucket findings](#)
- [Activating an archived bucket finding](#)
- [Viewing finding details](#)
- [Downloading an IAM Access Analyzer for S3 report](#)

What information does IAM Access Analyzer for S3 provide?

IAM Access Analyzer for S3 provides findings for buckets that can be accessed outside your AWS account. Buckets that are listed under **Buckets with public access** can be accessed by anyone on the internet. If IAM Access Analyzer for S3 identifies public buckets, you also see a warning at the top of the page that shows you the number of public buckets in your Region. Buckets listed under **Buckets with access from other AWS accounts — including third-party AWS accounts** are shared conditionally with other AWS accounts, including accounts outside of your organization.

For each bucket, IAM Access Analyzer for S3 provides the following information:

- **Bucket name**
- **Discovered by Access analyzer** - When IAM Access Analyzer for S3 discovered the public or shared bucket access.
- **Shared through** - How the bucket is shared—through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy. Multi-Region Access Points and cross-account access points are reflected under access points. A bucket can be shared through both policies and ACLs. If you want to find and review the source for your bucket access, you can use the information in this column as a starting point for taking immediate and precise corrective action.
- **Status** - The status of the bucket finding. IAM Access Analyzer for S3 displays findings for all public and shared buckets.
 - **Active** - Finding has not been reviewed.
 - **Archived** - Finding has been reviewed and confirmed as intended.
 - **All** - All findings for buckets that are public or shared with other AWS accounts, including AWS accounts outside of your organization.
- **Access level** - Access permissions granted for the bucket:
 - **List** - List resources.
 - **Read** - Read but not edit resource contents and attributes.
 - **Write** - Create, delete, or modify resources.
 - **Permissions** - Grant or modify resource permissions.
 - **Tagging** - Update tags associated with the resource.

Enabling IAM Access Analyzer for S3

To use IAM Access Analyzer for S3, you must complete the following prerequisite steps.

1. Grant the required permissions.

For more information, see [Permissions Required to use IAM Access Analyzer](#) in the *IAM User Guide*.

2. Visit IAM to create an account-level analyzer for each Region where you want to use IAM Access Analyzer.

IAM Access Analyzer for S3 requires an account-level analyzer. To use IAM Access Analyzer for S3, you must create an analyzer that has an account as the zone of trust. For more information, see [Enabling IAM Access Analyzer](#) in *IAM User Guide*.

Blocking all public access

If you want to block all access to a bucket in a single click, you can use the **Block all public access** button in IAM Access Analyzer for S3. When you block all public access to a bucket, no public access is granted. We recommend that you block all public access to your buckets unless you require public access to support a specific and verified use case. Before you block all public access, ensure that your applications will continue to work correctly without public access.

If you don't want to block all public access to your bucket, you can edit your block public access settings on the Amazon S3 console to configure granular levels of access to your buckets. For more information, see [Blocking public access to your Amazon S3 storage](#).

In rare cases, IAM Access Analyzer for S3 and Amazon S3 block public access evaluation might differ on whether a bucket is public. This behavior occurs because Amazon S3 block public access performs validation on the existence of actions in addition to evaluating public access. Suppose that the bucket policy contains an Action statement that allows public access for an action that isn't supported by Amazon S3 (for example, s3 : NotASupportedAction). In this case, Amazon S3 block public access evaluates the bucket as public because such a statement could potentially make the bucket public if the action later becomes supported. In cases where Amazon S3 block public access and IAM Access Analyzer for S3 differ in their evaluations, we recommend reviewing the bucket policy and removing any unsupported actions.

To block all public access to a bucket using IAM Access Analyzer for S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane on the left, under **Dashboards**, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **Block all public access**.
5. To confirm your intent to block all public access to the bucket, in **Block all public access (bucket settings)**, enter **confirm**.

Amazon S3 blocks all public access to your bucket. The status of the bucket finding updates to **resolved**, and the bucket disappears from the IAM Access Analyzer for S3 listing. If you want to review resolved buckets, open IAM Access Analyzer on the [IAM Console](#).

Reviewing and changing bucket access

If you did not intend to grant access to the public or other AWS accounts, including accounts outside of your organization, you can modify the bucket ACL, bucket policy, the Multi-Region Access Point policy, or the access point policy to remove the access to the bucket. The **Shared through** column shows all sources of bucket access: bucket policy, bucket ACL, and/or access point policy. Multi-Region Access Points and cross-account access points are reflected under access points.

To review and change a bucket policy, a bucket ACL, a Multi-Region Access Point, or an access point policy

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. To see whether public access or shared access is granted through a bucket policy, a bucket ACL, a Multi-Region Access Point policy, or an access point policy, look in the **Shared through** column.
4. Under **Buckets**, choose the name of the bucket with the bucket policy, bucket ACL, Multi-Region Access Point policy, or access point policy that you want to change or review.
5. If you want to change or view a bucket ACL:
 - a. Choose **Permissions**.
 - b. Choose **Access Control List**.
 - c. Review your bucket ACL, and make changes as required.

For more information, see [Configuring ACLs](#).

6. If you want to change or review a bucket policy:
 - a. Choose **Permissions**.
 - b. Choose **Bucket Policy**.
 - c. Review or change your bucket policy as required.

For more information, see [Adding a bucket policy by using the Amazon S3 console](#).

7. If you want to change or view a Multi-Region Access Point policy:

- a. Choose **Multi-Region Access Point**.
- b. Choose the Multi-Region Access Point name.
- c. Review or change your Multi-Region Access Point policy as required.

For more information, see [Permissions](#).

8. If you want to review or change an access point policy:

- a. Choose **access points**.
- b. Choose the access point name.
- c. Review or change access as required.

For more information, see [Managing your Amazon S3 access points](#).

If you edit or remove a bucket ACL, a bucket policy, or an access point policy to remove public or shared access, the status for the bucket findings updates to resolved. The resolved bucket findings disappear from the IAM Access Analyzer for S3 listing, but you can view them in IAM Access Analyzer.

Archiving bucket findings

If a bucket grants access to the public or other AWS accounts, including accounts outside of your organization, to support a specific use case (for example, a static website, public downloads, or cross-account sharing), you can archive the finding for the bucket. When you archive bucket findings, you acknowledge and record your intent for the bucket to remain public or shared. Archived bucket findings remain in your IAM Access Analyzer for S3 listing so that you always know which buckets are public or shared.

To archive bucket findings in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose an active bucket.

4. To acknowledge your intent for this bucket to be accessed by the public or other AWS accounts, including accounts outside of your organization, choose **Archive**.
5. Enter **confirm**, and choose **Archive**.

Activating an archived bucket finding

After you archive findings, you can always revisit them and change their status back to active, indicating that the bucket requires another review.

To activate an archived bucket finding in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. Choose the archived bucket findings.
4. Choose **Mark as active**.

Viewing finding details

If you need to see more information about a bucket, you can open the bucket finding details in IAM Access Analyzer on the [IAM Console](#).

To view finding details in IAM Access Analyzer for S3

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Access analyzer for S3**.
3. In IAM Access Analyzer for S3, choose a bucket.
4. Choose **View details**.

The finding details open in IAM Access Analyzer on the [IAM Console](#).

Downloading an IAM Access Analyzer for S3 report

You can download your bucket findings as a CSV report that you can use for auditing purposes. The report includes the same information that you see in IAM Access Analyzer for S3 on the Amazon S3 console.

To download a report

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane on the left, choose **Access analyzer for S3**.
3. In the Region filter, choose the Region.

IAM Access Analyzer for S3 updates to shows buckets for the chosen Region.

4. Choose **Download report**.

A CSV report is generated and saved to your computer.

Verifying bucket ownership with bucket owner condition

Amazon S3 bucket owner condition ensures that the buckets you use in your S3 operations belong to the AWS accounts that you expect.

Most S3 operations read from or write to specific S3 buckets. These operations include uploading, copying, and downloading objects, retrieving or modifying bucket configurations, and retrieving or modifying object configurations. When you perform these operations, you specify the bucket that you want to use by including its name with the request. For example, to retrieve an object from S3, you make a request that specifies the name of a bucket and the object key to retrieve from that bucket.

Because Amazon S3 identifies buckets based on their names, an application that uses an incorrect bucket name in a request could inadvertently perform operations against a different bucket than expected. To help avoid unintentional bucket interactions in situations like this, you can use *bucket owner condition*. Bucket owner condition enables you to verify that the target bucket is owned by the expected AWS account, providing an additional layer of assurance that your S3 operations are having the effects you intend.

Topics

- [When to use bucket owner condition](#)
- [Verifying a bucket owner](#)
- [Examples](#)
- [Restrictions and limitations](#)

When to use bucket owner condition

We recommend using bucket owner condition whenever you perform a supported S3 operation and know the account ID of the expected bucket owner. Bucket owner condition is available for all S3 object operations and most S3 bucket operations. For a list of S3 operations that don't support bucket owner condition, see [Restrictions and limitations](#).

To see the benefit of using bucket owner condition, consider the following scenario involving AWS customer Bea:

1. Bea develops an application that uses Amazon S3. During development, Bea uses her testing-only AWS account to create a bucket named `bea-data-test`, and configures her application to make requests to `bea-data-test`.
2. Bea deploys her application, but forgets to reconfigure the application to use a bucket in her production AWS account.
3. In production, Bea's application makes requests to `bea-data-test`, which succeed. This results in production data being written to the bucket in Bea's test account.

Bea can help protect against situations like this by using bucket owner condition. With bucket owner condition, Bea can include the AWS account ID of the expected bucket owner in her requests. Amazon S3 then checks the account ID of the bucket owner before processing each request. If the actual bucket owner doesn't match the expected bucket owner, the request fails.

If Bea uses bucket owner condition, the scenario described earlier won't result in Bea's application inadvertently writing to a test bucket. Instead, the requests that her application makes at step 3 will fail with an `Access Denied` error message. By using bucket owner condition, Bea helps eliminate the risk of accidentally interacting with buckets in the wrong AWS account.

Verifying a bucket owner

To use bucket owner condition, you include a parameter with your request that specifies the expected bucket owner. Most S3 operations involve only a single bucket, and require only this single parameter to use bucket owner condition. For `CopyObject` operations, this first parameter specifies the expected owner of the destination bucket, and you include a second parameter to specify the expected owner of the source bucket.

When you make a request that includes a bucket owner condition parameter, S3 checks the account ID of the bucket owner against the specified parameter before processing the request. If the

parameter matches the bucket owner's account ID, S3 processes the request. If the parameter doesn't match the bucket owner's account ID, the request fails with an Access Denied error message.

You can use bucket owner condition with the AWS Command Line Interface (AWS CLI), AWS SDKs, and Amazon S3 REST APIs. When using bucket owner condition with the AWS CLI and Amazon S3 REST APIs, use the following parameter names.

Access method	Parameter for non-copy operations	Copy operation source parameter	Copy operation destination parameter
AWS CLI	--expected-bucket-owner	--expected-source-bucket-owner	--expected-bucket-owner
Amazon S3 REST APIs	x-amz-expected-bucket-owner header	x-amz-source-expected-bucket-owner header	x-amz-expected-bucket-owner header

The parameter names that are required to use bucket owner condition with the AWS SDKs vary depending on the language. To determine the required parameters, see the SDK documentation for your desired language. You can find the SDK documentation at [Tools to Build on AWS](#).

Examples

The following examples show how you can implement bucket owner condition in Amazon S3 using the AWS CLI or the AWS SDK for Java 2.x.

Example

Example: Upload an object

The following example uploads an object to S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api put-object \  
    --bucket amzn-s3-demo-bucket1 --key exampleobject --  
body example_file.txt \  
    --expected-bucket-owner 111122223333
```

AWS SDK for Java 2.x

```
public void putObjectExample() {  
    S3Client s3Client = S3Client.create();;  
    PutObjectRequest request = PutObjectRequest.builder()  
        .bucket("amzn-s3-demo-bucket1")  
        .key("exampleobject")  
        .expectedBucketOwner("111122223333")  
        .build();  
    Path path = Paths.get("example_file.txt");  
    s3Client.putObject(request, path);  
}
```

Example

Example: Copy an object

The following example copies the object `object1` from S3 bucket `amzn-s3-demo-bucket1` to S3 bucket `amzn-s3-demo-bucket2`. It uses bucket owner condition to ensure that the buckets are owned by the expected accounts according to the following table.

Bucket	Expected owner
amzn-s3-demo-bucket1	111122223333
amzn-s3-demo-bucket2	444455556666

AWS CLI

```
aws s3api copy-object --copy-source amzn-s3-demo-bucket1/object1 \  
    --bucket amzn-s3-demo-bucket2 --key object1copy \  

```

```
--expected-source-bucket-owner 111122223333 --expected-
bucket-owner 444455556666
```

AWS SDK for Java 2.x

```
public void copyObjectExample() {
    S3Client s3Client = S3Client.create();
    CopyObjectRequest request = CopyObjectRequest.builder()
        .copySource("amzn-s3-demo-bucket1/object1")
        .destinationBucket("amzn-s3-demo-bucket2")
        .destinationKey("object1copy")
        .expectedSourceBucketOwner("111122223333")
        .expectedBucketOwner("444455556666")
        .build();
    s3Client.copyObject(request);
}
```

Example

Example: Retrieve a bucket policy

The following example retrieves the access policy for S3 bucket *amzn-s3-demo-bucket1*, using bucket owner condition to ensure that *amzn-s3-demo-bucket1* is owned by AWS account 111122223333.

AWS CLI

```
aws s3api get-bucket-policy --bucket amzn-s3-demo-bucket1 --expected-bucket-
owner 111122223333
```

AWS SDK for Java 2.x

```
public void getBucketPolicyExample() {
    S3Client s3Client = S3Client.create();
    GetBucketPolicyRequest request = GetBucketPolicyRequest.builder()
        .bucket("amzn-s3-demo-bucket1")
        .expectedBucketOwner("111122223333")
        .build();
    try {
        GetBucketPolicyResponse response = s3Client.getBucketPolicy(request);
    }
}
```

```
        catch (S3Exception e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it, so it returned an error response.
            e.printStackTrace();
        }
    }
```

Restrictions and limitations

Amazon S3 bucket owner condition has the following restrictions and limitations:

- The value of the bucket owner condition parameter must be an AWS account ID (12-digit numeric value). Service principals aren't supported.
- Bucket owner condition isn't available for [CreateBucket](#), [ListBuckets](#), or any of the operations included in [AWS S3 Control](#). Amazon S3 ignores any bucket owner condition parameters included with requests to these operations.
- Bucket owner condition only verifies that the account specified in the verification parameter owns the bucket. Bucket owner condition doesn't check the configuration of the bucket. It also doesn't guarantee that the bucket's configuration meets any specific conditions or matches any past state.

Controlling ownership of objects and disabling ACLs for your bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable [access control lists \(ACLs\)](#). By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you keep ACLs disabled except in unusual circumstances where you must control access for each object individually. With ACLs disabled, you can use policies to more easily control access to every object in your bucket, regardless of who uploaded the objects in your bucket.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

For the majority of modern use cases in S3, we recommend that you keep ACLs disabled by applying the Bucket owner enforced setting and using your bucket policy to share data with users outside of your account as needed. This approach simplifies permissions management. You can disable ACLs on both newly created and already existing buckets. For newly created buckets, ACLs are disabled by default. In the case of an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of an access evaluation, and access is granted or denied on the basis of policies. For existing buckets, you can re-enable ACLs at any time after you disable them, and your preexisting bucket and object ACLs are restored.

Before you disable ACLs, we recommend that you review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account. After you disable ACLs, your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs, for example, the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL expressed in XML. Existing applications that support bucket owner full control ACLs see no impact. PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return a 400 error with the error code `AccessControlListNotSupported`.

In contrast, a bucket with the Bucket owner preferred setting continues to accept and honor bucket and object ACLs. With this setting, new objects that are written with the `bucket-owner-full-control` canned ACL are automatically owned by the bucket owner rather than the object writer. All other ACL behaviors remain in place. To require all Amazon S3 PUT operations to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that allows only object uploads using this ACL.

To see which Object Ownership settings are applied to your buckets, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to find Object Ownership settings](#).

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Object Ownership settings

This table shows the impact that each Object Ownership setting has on ACLs, objects, object ownership, and object uploads.

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
Bucket owner enforced (default)	All new and existing objects	Bucket owner owns every object.	ACLs are disabled and no longer affect access permissions to your bucket. Requests to set or update ACLs fail. However, requests to read ACLs are supported.	Uploads with bucket owner full control ACLs or uploads that don't specify an ACL

Setting	Applies to	Effect on object ownership	Effect on ACLs	Uploads accepted
			Object writer no longer has full ownership and control.	
Bucket owner preferred	New objects	<p>If an object upload includes the <code>bucket-owner-full-control</code> canned ACL, the bucket owner owns the object.</p> <p>Objects uploaded with other ACLs are owned by the writing account.</p>	<p>ACLs can be updated and can grant permissions.</p> <p>If an object upload includes the <code>bucket-owner-full-control</code> canned ACL, the bucket owner has full control access, and the object writer no longer has full control access.</p>	All uploads
Object writer	New objects	<p>Object writer owns the object.</p>	<p>ACLs can be updated and can grant permissions.</p> <p>Object writer has full control access.</p>	All uploads

Changes introduced by disabling ACLs

When the Bucket owner enforced setting for Object Ownership is applied, ACLs are disabled and you automatically own and take full control over every object in the bucket without taking any additional actions. Bucket owner enforced is the default setting for all newly created buckets. After the Bucket owner enforced setting is applied, you will see three changes:

- All bucket ACLs and object ACLs are disabled, which gives full access to you, as the bucket owner. When you perform a read ACL request on your bucket or object, you will see that full access is given only to the bucket owner.
- You, as the bucket owner, automatically own and have full control over every object in your bucket.
- ACLs no longer affect access permissions to your bucket. As a result, access control for your data is based on policies, such as AWS Identity and Access Management (IAM) [identity-based policies](#), Amazon S3 [bucket policies](#), VPC endpoint policies, and Organizations [service control policies \(SCPs\)](#) or [resource control policies \(RCPs\)](#).

If you use S3 Versioning, the bucket owner owns and has full control over all object versions in your bucket. Applying the Bucket owner enforced setting does not add a new version of an object.

New objects can be uploaded to your bucket only if they use bucket owner full control ACLs or don't specify an ACL. Object uploads fail if they specify any other ACL. For more information, see [Troubleshooting](#).

Because the following example PutObject operation using the AWS Command Line Interface (AWS CLI) includes the bucket-owner-full-control canned ACL, the object can be uploaded to a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file --acl bucket-owner-full-control
```

Because the following PutObject operation doesn't specify an ACL, it also succeeds for a bucket with disabled ACLs.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key key-name --body path-to-file
```

Note

If other AWS accounts need access to objects after uploading, you must grant additional permissions to those accounts through bucket policies. For more information, see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#).

Re-enabling ACLs

You can re-enable ACLs by changing from the Bucket owner enforced setting to another Object Ownership setting at any time. If you used object ACLs for permissions management before you applied the Bucket owner enforced setting and you didn't migrate these object ACL permissions to your bucket policy, after you re-enable ACLs, these permissions are restored. Additionally, objects written to the bucket while the Bucket owner enforced setting was applied are still owned by the bucket owner.

For example, if you change from the Bucket owner enforced setting back to the Object writer setting, you, as the bucket owner, no longer own and have full control over objects that were previously owned by other AWS accounts. Instead, the uploading accounts again own these objects.

Objects owned by other accounts use ACLs for permissions, so you can't use policies to grant permissions to these objects. However, you, as the bucket owner, still own any objects that were written to the bucket while the Bucket owner enforced setting was applied. These objects are not owned by the object writer, even if you re-enable ACLs.

For instructions on enabling and managing ACLs using the AWS Management Console, AWS Command Line Interface (CLI), REST API, or AWS SDKs, see [Configuring ACLs](#).

Prerequisites for disabling ACLs

Before you disable ACLs for an existing bucket, complete the following prerequisites.

Review bucket and object ACLs and migrate ACL permissions

When you disable ACLs, permissions granted by bucket and object ACLs no longer affect access. Before you disable ACLs, review your bucket and object ACLs.

If your bucket ACLs grant read or write permissions to others outside of your account, you must migrate these permissions to your bucket policy before you can apply the Bucket owner enforced setting. If you don't migrate bucket ACLs that grant read or write access outside of your account, your request to apply the Bucket owner enforced setting fails and returns the [InvalidBucketAclWithObjectOwnership](#) error code.

For example, if you want to disable ACLs for a bucket that receives server access logs, you must migrate the bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy. For more information, see [Grant access to the S3 log delivery group for server access logging](#).

If you want the object writer to maintain full control of the object that they upload, object writer is the best Object Ownership setting for your use case. If you want to control access at the individual object level, bucket owner preferred is the best choice. These use cases are uncommon.

To review ACLs and migrate ACL permissions to bucket policies, see [Prerequisites for disabling ACLs](#).

Identify requests that required an ACL for authorization

To identify Amazon S3 requests that required ACLs for authorization, you can use the `aclRequired` value in Amazon S3 server access logs or AWS CloudTrail. If the request required an ACL for authorization or if you have PUT requests that specify an ACL, the string is Yes. If no

ACLs were required, or if you are setting a bucket-owner-full-control canned ACL, or if the requests are allowed by your bucket policy, the aclRequired value string is "-" in Amazon S3 server access logs and is absent in CloudTrail. For more information about the expected aclRequired values, see [aclRequired values for common Amazon S3 requests](#).

If you have PutBucketAcl or PutObjectAcl requests with headers that grant ACL-based permissions, with the exception of the bucket-owner-full-control canned ACL, you must remove those headers before you can disable ACLs. Otherwise, your requests will fail.

For all other requests that required an ACL for authorization, migrate those ACL permissions to bucket policies. Then, remove any bucket ACLs before you enable the bucket owner enforced setting.

 **Note**

Do not remove object ACLs. Otherwise, applications that rely on object ACLs for permissions will lose access.

If you see that no requests required an ACL for authorization, you can proceed to disable ACLs. For more information about identifying requests, see [Using Amazon S3 server access logs to identify requests](#) and [Identifying Amazon S3 requests using CloudTrail](#).

Review and update bucket policies that use ACL-related condition keys

After you apply the Bucket owner enforced setting to disable ACLs, new objects can be uploaded to your bucket only if the request uses bucket owner full control ACLs or doesn't specify an ACL. Before disabling ACLs, review your bucket policy for ACL-related condition keys.

If your bucket policy uses an ACL-related condition key to require the bucket-owner-full-control canned ACL (for example, s3:x-amz-acl), you don't need to update your bucket policy. The following bucket policy uses the s3:x-amz-acl to require the bucket-owner-full-control canned ACL for S3 PutObject requests. This policy *still* requires the object writer to specify the bucket-owner-full-control canned ACL. However, buckets with ACLs disabled still accept this ACL, so requests continue to succeed with no client-side changes required.

```
{  
    "Version": "2012-10-17",  
    "Statement": [
```

```
{  
    "Sid": "Only allow writes to my bucket with bucket owner full control",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": [  
            "arn:aws:iam::111122223333:user/ExampleUser"  
        ]  
    },  
    "Action": [  
        "s3:PutObject"  
    ],  
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
    "Condition": {  
        "StringEquals": {  
            "s3:x-amz-acl": "bucket-owner-full-control"  
        }  
    }  
}  
]  
}
```

However, if your bucket policy uses an ACL-related condition key that requires a different ACL, you must remove this condition key. This example bucket policy requires the public-read ACL for S3 PutObject requests and therefore must be updated before disabling ACLs.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Only allow writes to my bucket with public read access",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ExampleUser"  
                ]  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": "public-read"  
                }  
            }  
        }  
    ]  
}
```

```
        }
    }
]
```

Object Ownership permissions

To apply, update, or delete an Object Ownership setting for a bucket, you need the `s3:PutBucketOwnershipControls` permission. To return the Object Ownership setting for a bucket, you need the `s3:GetBucketOwnershipControls` permission. For more information, see [Setting Object Ownership when you create a bucket](#) and [Viewing the Object Ownership setting for an S3 bucket](#).

Disabling ACLs for all new buckets

By default, all new buckets are created with the Bucket owner enforced setting applied and ACLs are disabled. We recommend keeping ACLs disabled. As a general rule, we recommend using S3 resource-based policies (bucket policies and access point policies) or IAM policies for access control instead of ACLs. Policies are a simplified and more flexible access control option. With bucket policies and access point policies, you can define rules that apply broadly across all requests to your Amazon S3 resources.

Replication and Object Ownership

When you use S3 replication and the source and destination buckets are owned by different AWS accounts, you can disable ACLs (with the Bucket owner enforced setting for Object Ownership) to change replica ownership to the AWS account that owns the destination bucket. This setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the Bucket owner enforced setting are owned by the destination bucket owner. For more information about the owner override option for replication configurations, see [Changing the replica owner](#).

Setting Object Ownership

You can apply an Object Ownership setting by using the Amazon S3 console, AWS CLI, AWS SDKs, Amazon S3 REST API, or AWS CloudFormation. The following REST API and AWS CLI commands support Object Ownership:

REST API	AWS CLI	Description
PutBucketOwnershipControls	put-bucket-ownership-controls	Creates or modifies the Object Ownership setting for an existing S3 bucket.
CreateBucket	create-bucket	Creates a bucket using the <code>x-amz-object-ownership</code> request header to specify the Object Ownership setting.
GetBucketOwnershipControls	get-bucket-ownership-controls	Retrieves the Object Ownership setting for an Amazon S3 bucket.
DeleteBucketOwnershipControls	delete-bucket-ownership-controls	Deletes the Object Ownership setting for an Amazon S3 bucket.

For more information about applying and working with Object Ownership settings, see the following topics.

Topics

- [Prerequisites for disabling ACLs](#)
- [Setting Object Ownership when you create a bucket](#)
- [Setting Object Ownership on an existing bucket](#)
- [Viewing the Object Ownership setting for an S3 bucket](#)
- [Disabling ACLs for all new buckets and enforcing Object Ownership](#)
- [Troubleshooting](#)

Prerequisites for disabling ACLs

If your bucket ACL grants access outside of your AWS account, before you disable ACLs, you must migrate your bucket ACL permissions to your bucket policy and reset your bucket ACL to the default private ACL. If you don't migrate these bucket ACLs, your request to apply the Bucket

owner enforced setting to disable ACLs fails and returns the [InvalidBucketAclWithObjectOwnership](#) error code. We also recommend that you review your object ACL permissions and migrate them to your bucket policy. For more information about other suggested prerequisites, see [Prerequisites for disabling ACLs](#).

Each of your existing bucket and object ACLs has an equivalent in an IAM policy. The following bucket policy examples show you how READ and WRITE permissions for bucket and object ACLs map to IAM permissions. For more information about how each ACL translates to IAM permissions, see [Mapping of ACL permissions and access policy permissions](#).

To review and migrate ACL permissions to bucket policies, see the following topics.

Topics

- [Bucket policies examples](#)
- [Using the S3 console to review and migrate ACL permissions](#)
- [Using the AWS CLI to review and migrate ACL permissions](#)
- [Example walkthroughs](#)

Bucket policies examples

These example bucket policies show you how to migrate READ and WRITE bucket and object ACL permissions for a third-party AWS account to a bucket policy. READ_ACP and WRITE_ACP ACLs are less relevant for policies because they grant ACL-related permissions (s3:GetBucketAcl, s3:GetObjectAcl, s3:PutBucketAcl, and s3:PutObjectAcl).

Example – READ ACL for a bucket

If your bucket had a READ ACL that grants AWS account **111122223333** permission to list the contents of your bucket, you can write a bucket policy that grants s3>ListBucket, s3>ListBucketVersions, s3>ListBucketMultipartUploads permissions for your bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Permission to list the objects in a bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "111122223333"  
            }  
        }  
    ]  
}
```

```
"AWS": [  
    "arn:aws:iam::111122223333:root"  
],  
},  
"Action": [  
    "s3>ListBucket",  
    "s3>ListBucketVersions",  
    "s3>ListBucketMultipartUploads"  
],  
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket"  
}  
]  
}
```

Example – READ ACLs for every object in a bucket

If every object in your bucket has a READ ACL that grants access to AWS account **111122223333**, you can write a bucket policy that grants s3:GetObject and s3:GetObjectVersion permissions to this account for every object in your bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Read permission for every object in a bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root"  
                ]  
            },  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"  
        }  
    ]  
}
```

This example resource element grants access to a specific object.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

Example – WRITE ACL that grants permissions to write objects to a bucket

If your bucket has a WRITE ACL that grants AWS account **111122223333** permission to write objects to your bucket, you can write a bucket policy that grants s3:PutObject permission for your bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Permission to write objects to a bucket",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root"
                ]
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Using the S3 console to review and migrate ACL permissions

To review a bucket's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name.
3. Choose the **Permissions** tab.
4. Under **Access control list (ACL)**, review your bucket ACL permissions.

To review an object's ACL permissions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name containing your object.
3. In the **Objects** list, choose your object name.
4. Choose the **Permissions** tab.
5. Under **Access control list (ACL)**, review your object ACL permissions.

To migrate ACL permissions and update your bucket ACL

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket name.
3. On the **Permissions** tab, under **Bucket policy**, choose **Edit**.
4. In the **Policy** box, add or update your bucket policy.

For example bucket policies, see [Bucket policies examples](#) and [Example walkthroughs](#).

5. Choose **Save changes**.
6. [Update your bucket ACL](#) to remove ACL grants to other groups or AWS accounts.
7. [Apply the Bucket owner enforced setting](#) for Object Ownership.

Using the AWS CLI to review and migrate ACL permissions

1. To return the bucket ACL for your bucket, use the [get-bucket-acl](#) AWS CLI command:

```
aws s3api get-bucket-acl --bucket amzn-s3-demo-bucket
```

For example, this bucket ACL grants WRITE and READ access to a third-party account. In this ACL, the third-party account is identified by the [canonical user ID](#). To apply the Bucket owner enforced setting and disable ACLs, you must migrate these permissions for the third-party account to a bucket policy.

```
{  
    "Owner": {
```

```
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
    },
    "Grants": [
        {
            "Grantee": {
                "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
                "ID":
"852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "FULL_CONTROL"
        },
        {
            "Grantee": {
                "DisplayName": "THIRD-PARTY-EXAMPLE-ACCOUNT",
                "ID":
"72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "READ"
        },
        {
            "Grantee": {
                "DisplayName": "THIRD-PARTY-EXAMPLE-ACCOUNT",
                "ID":
"72806de9d1ae8b171cca9e2494a8d1335dfced4ThirdPartyAccountCanonicalUserID",
                "Type": "CanonicalUser"
            },
            "Permission": "WRITE"
        }
    ]
}
```

For other example ACLs, see [Example walkthroughs](#).

2. Migrate your bucket ACL permissions to a bucket policy:

This example bucket policy grants s3:PutObject and s3>ListBucket permissions for a third-party account. In the bucket policy, the third-party account is identified by the AWS account ID ([111122223333](#)).

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://  
policy.json
```

policy.json:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PolicyForCrossAccountAllowUpload",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:root"  
                ]  
            },  
            "Action": [  
                "s3:PutObject",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket",  
                "arn:aws:s3:::amzn-s3-demo-bucket/*"  
            ]  
        }  
    ]  
}
```

For more example bucket policies, see [Bucket policies examples](#) and [Example walkthroughs](#).

3. To return the ACL for a specific object, use the [get-object-acl](#) AWS CLI command.

```
aws s3api get-object-acl --bucket amzn-s3-demo-bucket --key EXAMPLE-OBJECT-KEY
```

4. If required, migrate object ACL permissions to your bucket policy.

This example resource element grants access to a specific object in a bucket policy.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-OBJECT-KEY"
```

5. Reset the ACL for your bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

6. Apply the Bucket owner enforced setting for Object Ownership.

Example walkthroughs

The following examples show you how to migrate ACL permissions to bucket policies for specific use cases.

Topics

- Grant access to the S3 log delivery group for server access logging
 - Grant public read access to the objects in a bucket
 - Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

Grant access to the S3 log delivery group for server access logging

If you want to apply the Bucket owner enforced setting to disable ACLs for a server access logging destination bucket (also known as a *target bucket*), you must migrate bucket ACL permissions for the S3 log delivery group to the logging service principal (`logging.s3.amazonaws.com`) in a bucket policy. For more information about log delivery permissions, see [Permissions for log delivery](#).

This bucket ACL grants WRITE and READ_ACP access to the S3 log delivery group:

```
{  
  "Owner": {  
    "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",  
    "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
  },  
  "Grants": [  
    {  
      "Grantee": {  
        "Type": "CanonicalUser",  
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",  
        "ID":  
"852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
      },  
      "Permission": "FULL_CONTROL"  
    },  
    {  
      "Grantee": {  
        "Type": "Group",  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
      },  
      "Permission": "READ_ACP"  
    }  
  ]  
}
```

```
        "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
    },
    "Permission": "WRITE"
},
{
    "Grantee": {
        "Type": "Group",
        "URI": "http://acs.amazonaws.com/groups/s3/LogDelivery"
    },
    "Permission": "READ_ACP"
}
]
```

To migrate bucket ACL permissions for the S3 log delivery group to the logging service principal in a bucket policy

1. Add the following bucket policy to your destination bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy file://  
policy.json

policy.json:      {
  {
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3ServerAccessLogsPolicy",
      "Effect": "Allow",
      "Principal": {
        "Service": "logging.s3.amazonaws.com"
      },
      "Action": [
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/EXAMPLE-LOGGING-PREFIX*",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::SOURCE-BUCKET-NAME"
        },
        "StringEquals": {
          "aws:SourceAccount": "SOURCE-AWS-ACCOUNT-ID"
        }
      }
    }
  ]
}
```

```
        }
    ]
}
```

2. Reset the ACL for your destination bucket to the default ACL.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. [Apply the Bucket owner enforced setting](#) for Object Ownership to your destination bucket.

Grant public read access to the objects in a bucket

If your object ACLs grant public read access to all of the objects in your bucket, you can migrate these ACL permissions to a bucket policy.

This object ACL grants public read access to an object in a bucket:

```
{
  "Owner": {
    "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
    "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"
  },
  "Grants": [
    {
      "Grantee": {
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",
        "Type": "CanonicalUser"
      },
      "Permission": "FULL_CONTROL"
    },
    {
      "Grantee": {
        "Type": "Group",
        "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
      },
      "Permission": "READ"
    }
  ]
}
```

To migrate public read ACL permissions to a bucket policy

1. To grant public read access to all of the objects in your bucket, add the following bucket policy, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy  
file://policy.json

policy.json:  
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket/*"  
            ]  
        }  
    ]  
}
```

To grant public access to a specific object in a bucket policy, use the following format for the Resource element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/OBJECT-KEY"
```

To grant public access to all of the objects with a specific prefix, use the following format for the Resource element.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/PREFIX/*"
```

2. Apply the Bucket owner enforced setting for Object Ownership.

Grant Amazon ElastiCache (Redis OSS) access to your S3 bucket

You can [export your ElastiCache \(Redis OSS\) backup](#) to an S3 bucket, which gives you access to the backup from outside ElastiCache. To export your backup to an S3 bucket, you must grant ElastiCache permissions to copy a snapshot to the bucket. If you've granted permissions to ElastiCache in a bucket ACL, you must migrate these permissions to a bucket policy before you apply the Bucket owner enforced setting to disable ACLs. For more information, see [Grant ElastiCache access to your Amazon S3 bucket](#) in the *Amazon ElastiCache User Guide*.

The following example shows the bucket ACL permissions that grant permissions to ElastiCache.

```
{  
    "Owner": {  
        "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
    },  
    "Grants": [  
        {  
            "Grantee": {  
                "DisplayName": "DOC-EXAMPLE-ACCOUNT-OWNER",  
                "ID":  
"852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "FULL_CONTROL"  
        },  
        {  
            "Grantee": {  
                "DisplayName": "aws-scs-s3-readonly",  
                "ID":  
"540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "READ"  
        },  
        {  
            "Grantee": {  
                "DisplayName": "aws-scs-s3-readonly",  
                "ID":  
"540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "WRITE"  
        }  
    ]  
}
```

```
},
{
    "Grantee": {
        "DisplayName": "aws-scs-s3-readonly",
        "ID": "540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353",
        "Type": "CanonicalUser"
    },
    "Permission": "READ_ACP"
}
]
}
```

To migrate bucket ACL permissions for ElastiCache (Redis OSS) to a bucket policy

1. Add the following bucket policy to your bucket, replacing the example values.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-bucket --policy
file://policy.json

policy.json:
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Stmt15399483",
            "Effect": "Allow",
            "Principal": {
                "Service": "Region.elasticache-snapshot.amazonaws.com"
            },
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3>ListBucket",
                "s3:GetBucketAcl",
                "s3>ListMultipartUploadParts",
                "s3>ListBucketMultipartUploads"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

```
]  
}
```

2. Reset the ACL for your bucket to the default ACL:

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --acl private
```

3. [Apply the Bucket owner enforced setting](#) for Object Ownership.

Setting Object Ownership when you create a bucket

When you create a bucket, you can configure S3 Object Ownership. To set Object Ownership for an existing bucket, see [Setting Object Ownership on an existing bucket](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Permissions: To apply the **Bucket owner enforced** setting or the **Bucket owner preferred** setting, you must have the following permissions: `s3:CreateBucket` and `s3:PutBucketOwnershipControls`. No additional permissions are needed when creating a bucket with the **Object writer** setting applied. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Important

A majority of modern use cases in Amazon S3 no longer require the use of ACLs, and we recommend that you disable ACLs except in unusual circumstances where you need to control access for each object individually. With Object Ownership, you can disable ACLs and rely on policies for access control. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts. You, as the bucket owner, own all the objects in the bucket and can manage access to them using policies.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket.

The bucket name must:

- Be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions).
- Be between 3 and 63 characters long.
- Consist only of lowercase letters, numbers, dots (.), and hyphens (-). For best compatibility, we recommend that you avoid using dots (.) in bucket names, except for buckets that are used only for static website hosting.
- Begin and end with a letter or number.

After you create the bucket, you cannot change its name. The AWS account that creates the bucket owns it. For more information about naming buckets, see [General purpose bucket naming rules](#).

 **Important**

Avoid including sensitive information, such as account numbers, in the bucket name.
The bucket name is visible in the URLs that point to the objects in the bucket.

6. AWS Management Console allows you to copy an existing bucket's settings to your new bucket. If you do not want to copy the settings of an existing bucket, skip to the next step.

 **Note**

This option:

- Is not available in the AWS CLI and is only available in console
- Is not available for directory buckets
- Does not copy the bucket policy from the existing bucket to the new bucket

To copy an existing bucket's settings, under **Copy settings from existing bucket**, select **Choose bucket**. The **Choose bucket** window opens. Find the bucket with the settings that you would like to copy, and select **Choose bucket**. The **Choose bucket** window closes, and the **Create bucket** window re-opens.

Under **Copy settings from existing bucket**, you will now see the name of the bucket you selected. You will also see a **Restore defaults** option that you can use to remove the copied bucket settings. Review the remaining bucket settings, on the **Create bucket** page. You will see that they now match the settings of the bucket that you selected. You can skip to the final step.

7. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect access permissions to data in the S3 bucket. The bucket uses policies exclusively to define access control.

By default, ACLs are disabled. A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.

If you apply the **Bucket owner preferred** setting, to require all Amazon S3 uploads to include the `bucket-owner-full-control` canned ACL, you can [add a bucket policy](#) that allows only object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Note

The default setting is **Bucket owner enforced**. To apply the default setting and keep ACLs disabled, only the `s3:CreateBucket` permission is needed. To enable ACLs, you must have the `s3:PutBucketOwnershipControls` permission.

- Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.

By default, all four Block Public Access settings are enabled. We recommend that you keep all settings enabled, unless you know that you need to turn off one or more of them for your specific use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

 **Note**

To enable all Block Public Access settings, only the `s3:CreateBucket` permission is required. To turn off any Block Public Access settings, you must have the `s3:PutBucketPublicAccessBlock` permission.

- (Optional) Under **Bucket Versioning**, you can choose if you wish to keep variants of objects in your bucket. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

To disable or enable versioning on your bucket, choose either **Disable** or **Enable**.

- (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs used to categorize storage.

To add a bucket tag, enter a **Key** and optionally a **Value** and choose **Add Tag**.

- Under **Default encryption**, choose **Edit**.

- To configure default encryption, under **Encryption type**, choose one of the following:

- Amazon S3 managed key (SSE-S3)**
- AWS Key Management Service key (SSE-KMS)**

 **Important**

If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quota of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the [AWS Key Management Service Developer Guide](#).

Buckets and new objects are encrypted with server-side encryption with an **Amazon S3 managed key** as the base level of encryption configuration. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about using Amazon S3 server-side encryption to encrypt your data, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

13. If you chose **AWS Key Management Service key (SSE-KMS)**, do the following:

a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN. For more information on cross account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*. For more information on SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#).

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

14. (Optional) If you want to enable S3 Object Lock, do the following:

- a. Choose **Advanced settings**.

 **Important**

Enabling Object Lock also enables versioning for the bucket. After enabling you must configure the Object Lock default retention and legal hold settings to protect new objects from being deleted or overwritten.

- b. If you want to enable Object Lock, choose **Enable**, read the warning that appears, and acknowledge it.

For more information, see [Locking objects with Object Lock](#).

 **Note**

To create an Object Lock enabled bucket, you must have the following permissions: `s3:CreateBucket`, `s3:PutBucketVersioning` and `s3:PutBucketObjectLockConfiguration`.

15. Choose **Create bucket**.

Using the AWS CLI

To set Object Ownership when you create a new bucket, use the `create-bucket` AWS CLI command with the `--object-ownership` parameter.

This example applies the Bucket owner enforced setting for a new bucket using the AWS CLI:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket --region us-east-1 --object-ownership BucketOwnerEnforced
```

Important

If you don't set Object Ownership when you create a bucket by using the AWS CLI, the default setting will be `ObjectWriter` (ACLs enabled).

Using the AWS SDK for Java

This example sets the Bucket owner enforced setting for a new bucket using the AWS SDK for Java:

```
// Build the ObjectOwnership for CreateBucket
CreateBucketRequest createBucketRequest = CreateBucketRequest.builder()
    .bucket(bucketName)
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
    .build()

// Send the request to Amazon S3
s3client.createBucket(createBucketRequest);
```

Using AWS CloudFormation

To use the `AWS::S3::Bucket` AWS CloudFormation resource to set Object Ownership when you create a new bucket, see [OwnershipControls within AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To apply the Bucket owner enforced setting for S3 Object Ownership, use the [CreateBucket](#) API operation with the `x-amz-object-ownership` request header set to `BucketOwnerEnforced`. For information and examples, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- [Bucket owner preferred](#) – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Setting Object Ownership on an existing bucket

You can configure S3 Object Ownership on an existing S3 bucket. To apply Object Ownership when you create a bucket, see [Setting Object Ownership when you create a bucket](#).

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the `bucket-owner-full-control` canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

Prerequisites: Before you apply the Bucket owner enforced setting to disable ACLs, you must migrate bucket ACL permissions to bucket policies and reset your bucket ACLs to the default private ACL. We also recommend that you migrate object ACL permissions to bucket policies and edit bucket policies that require ACLs other than bucket owner full control ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Permissions: To use this operation, you must have the `s3:PutBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an S3 Object Ownership setting to.
3. Choose the **Permissions** tab.
4. Under **Object Ownership**, choose **Edit**.
5. Under **Object Ownership**, to disable or enable ACLs and control ownership of objects uploaded in your bucket, choose one of the following settings:

ACLs disabled

- **Bucket owner enforced** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

To require that all new buckets are created with ACLs disabled by using IAM or AWS Organizations policies, see [Disabling ACLs for all new buckets \(bucket owner enforced\)](#).

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the bucket-owner-full-control canned ACL.

If you apply the bucket owner preferred setting, to require all Amazon S3 uploads to include the bucket-owner-full-control canned ACL, you can [add a bucket policy](#) that only allows object uploads that use this ACL.

- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

6. Choose **Save**.

Using the AWS CLI

To apply an Object Ownership setting for an existing bucket, use the `put-bucket-ownership-controls` command with the `--ownership-controls` parameter. Valid values for ownership are `BucketOwnerEnforced`, `BucketOwnerPreferred`, or `ObjectWriter`.

This example applies the Bucket owner enforced setting for an existing bucket by using the AWS CLI:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls="Rules=[{ObjectOwnership=BucketOwnerEnforced}]"
```

For information about `put-bucket-ownership-controls`, see [put-bucket-ownership-controls](#) in the *AWS Command Line Interface User Guide*.

Using the AWS SDK for Java

This example applies the `BucketOwnerEnforced` setting for Object Ownership on an existing bucket by using the AWS SDK for Java:

```
// Build the ObjectOwnership for BucketOwnerEnforced  
OwnershipControlsRule rule = OwnershipControlsRule.builder()  
    .objectOwnership(ObjectOwnership.BucketOwnerEnforced)
```

```
.build();

OwnershipControls ownershipControls = OwnershipControls.builder()
    .rules(rule)
    .build()

// Build the PutBucketOwnershipControlsRequest
PutBucketOwnershipControlsRequest putBucketOwnershipControlsRequest =
    PutBucketOwnershipControlsRequest.builder()
        .bucket(BUCKET_NAME)
        .ownershipControls(ownershipControls)
        .build();

// Send the request to Amazon S3
s3client.putBucketOwnershipControls(putBucketOwnershipControlsRequest);
```

Using AWS CloudFormation

To use AWS CloudFormation to apply an Object Ownership setting for an existing bucket, see [AWS::S3::Bucket OwnershipControls](#) in the *AWS CloudFormation User Guide*.

Using the REST API

To use the REST API to apply an Object Ownership setting to an existing S3 bucket, use `PutBucketOwnershipControls`. For more information, see [PutBucketOwnershipControls](#) in the *Amazon Simple Storage Service API Reference*.

Next steps: After you apply the Bucket owner enforced or bucket owner preferred settings for Object Ownership, you can further take the following steps:

- [Bucket owner enforced](#) – Require that all new buckets are created with ACLs disabled by using an IAM or Organizations policy.
- [Bucket owner preferred](#) – Add an S3 bucket policy to require the `bucket-owner-full-control` canned ACL for all object uploads to your bucket.

Viewing the Object Ownership setting for an S3 bucket

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket, simplifying access management for data stored in Amazon S3. By default, S3 Object Ownership is set to the Bucket owner enforced setting, and ACLs are disabled for new buckets. With ACLs disabled, the

bucket owner owns every object in the bucket and manages access to data exclusively by using access-management policies. We recommend that you keep ACLs disabled, except in unusual circumstances where you must control access for each object individually.

Object Ownership has three settings that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs:

ACLs disabled

- **Bucket owner enforced (default)** – ACLs are disabled, and the bucket owner automatically owns and has full control over every object in the bucket. ACLs no longer affect permissions to data in the S3 bucket. The bucket uses policies to define access control.

ACLs enabled

- **Bucket owner preferred** – The bucket owner owns and has full control over new objects that other accounts write to the bucket with the bucket-owner-full-control canned ACL.
- **Object writer** – The AWS account that uploads an object owns the object, has full control over it, and can grant other users access to it through ACLs.

You can view the S3 Object Ownership settings for an Amazon S3 bucket. To set Object Ownership for a new bucket, see [Setting Object Ownership when you create a bucket](#). To set Object Ownership for an existing bucket, see [Setting Object Ownership on an existing bucket](#).

Permissions: To use this operation, you must have the `s3:GetBucketOwnershipControls` permission. For more information about Amazon S3 permissions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to apply an Object Ownership setting to.
3. Choose the **Permissions** tab.

4. Under **Object Ownership**, you can view the Object Ownership settings for your bucket.

Using the AWS CLI

To retrieve the S3 Object Ownership setting for an S3 bucket, use the [get-bucket-ownership-controls](#) AWS CLI command.

```
aws s3api get-bucket-ownership-controls --bucket amzn-s3-demo-bucket
```

Using the REST API

To retrieve the Object Ownership setting for an S3 bucket, use the `GetBucketOwnershipControls` API operation. For more information, see [GetBucketOwnershipControls](#).

Disabling ACLs for all new buckets and enforcing Object Ownership

We recommend that you disable ACLs on your Amazon S3 buckets. You can do this by applying the Bucket owner enforced setting for S3 Object Ownership. When you apply this setting, ACLs are disabled and you automatically own and have full control over all objects in your bucket. To require that all new buckets are created with ACLs disabled, use AWS Identity and Access Management (IAM) policies or AWS Organizations service control policies (SCPs), as described in the next section.

To enforce object ownership for new objects without disabling ACLs, you can apply the Bucket owner preferred setting. When you apply this setting, we strongly recommend that you update your bucket policy to require the `bucket-owner-full-control` canned ACL for all PUT requests to your bucket. Make sure you also update your clients to send the `bucket-owner-full-control` canned ACL to your bucket from other accounts.

Topics

- [Disabling ACLs for all new buckets \(bucket owner enforced\)](#)
- [Requiring the `bucket-owner-full-control` canned ACL for Amazon S3 PUT operations \(bucket owner preferred\)](#)

Disabling ACLs for all new buckets (bucket owner enforced)

The following example IAM policy denies the `s3:CreateBucket` permission for a specific IAM user or role unless the Bucket owner enforced setting is applied for Object Ownership. The key-

value pair in the Condition block specifies s3:x-amz-object-ownership as its key and the BucketOwnerEnforced setting as its value. In other words, the IAM user can create buckets only if they set the Bucket owner enforced setting for Object Ownership and disable ACLs. You can also use this policy as a boundary SCP for your AWS organization.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "RequireBucketOwnerFullControl",  
            "Action": "s3/CreateBucket",  
            "Effect": "Deny",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-object-ownership": "BucketOwnerEnforced"  
                }  
            }  
        }  
    ]  
}
```

Requiring the bucket-owner-full-control canned ACL for Amazon S3 PUT operations (bucket owner preferred)

With the Bucket owner preferred setting for Object Ownership, you, as the bucket owner, own and have full control over new objects that other accounts write to your bucket with the bucket-owner-full-control canned ACL. However, if other accounts write objects to your bucket without the bucket-owner-full-control canned ACL, the object writer maintains full control access. You, as the bucket owner, can implement a bucket policy that allows writes only if they specify the bucket-owner-full-control canned ACL.

Note

If you have ACLs disabled with the Bucket owner enforced setting, you, as the bucket owner, automatically own and have full control over all the objects in your bucket. You don't need to use this section to update your bucket policy to enforce object ownership for the bucket owner.

The following bucket policy specifies that account **111122223333** can upload objects to **amzn-s3-demo-bucket** only when the object's ACL is set to `bucket-owner-full-control`. Be sure to replace **111122223333** with your account and **amzn-s3-demo-bucket** with the name of your bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Only allow writes to my bucket with bucket owner full control",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": [  
                    "arn:aws:iam::111122223333:user/ExampleUser"  
                ]  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringEquals": {  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

The following is an example copy operation that includes the `bucket-owner-full-control` canned ACL by using the AWS Command Line Interface (AWS CLI).

```
aws s3 cp file.txt s3://amzn-s3-demo-bucket --acl bucket-owner-full-control
```

After the bucket policy is put into effect, if the client does not include the `bucket-owner-full-control` canned ACL, the operation fails, and the uploader receives the following error:

An error occurred (AccessDenied) when calling the PutObject operation: Access Denied.

Note

If clients need access to objects after uploading, you must grant additional permissions to the uploading account. For information about granting accounts access to your resources, see [Walkthroughs that use policies to manage access to your Amazon S3 resources](#).

Troubleshooting

When you apply the Bucket owner enforced setting for S3 Object Ownership, access control lists (ACLs) are disabled and you, as the bucket owner, automatically own all objects in your bucket. ACLs no longer affect permissions for the objects in your bucket. You can use policies to grant permissions. All S3 PUT requests must either specify the `bucket-owner-full-control` canned ACL or not specify an ACL, or these requests will fail. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

If an invalid ACL is specified or bucket ACL permissions grant access outside of your AWS account, you might see the following error responses.

AccessControlListNotSupported

After you apply the Bucket owner enforced setting for Object Ownership, ACLs are disabled. Requests to set ACLs or update ACLs fail with a `400` error and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported. Requests to read ACLs always return a response that shows full control for the bucket owner. In your PUT operations, you must either specify bucket owner full control ACLs or not specify an ACL. Otherwise, your PUT operations fail.

The following example `put-object` AWS CLI command includes the `public-read` canned ACL.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object-key-name --body doc-example-body --acl public-read
```

If the bucket uses the Bucket owner enforced setting to disable ACLs, this operation fails, and the uploader receives the following error message:

An error occurred (`AccessControlListNotSupported`) when calling the `PutObject` operation: The bucket does not allow ACLs

InvalidBucketAclWithObjectOwnership

If you want to apply the Bucket owner enforced setting to disable ACLs, your bucket ACL must give full control only to the bucket owner. Your bucket ACL cannot give access to an external AWS account or any other group. For example, if your `CreateBucket` request sets Bucket owner enforced and specifies a bucket ACL that provides access to an external AWS account, your request fails with a `400` error and returns the `InvalidBucketAclWithObjectOwnership` error code. Similarly, if your `PutBucketOwnershipControls` request sets Bucket owner enforced on a bucket that has a bucket ACL that grants permissions to others, the request fails.

Example : Existing bucket ACL grants public read access

For example, if an existing bucket ACL grants public read access, you cannot apply the Bucket owner enforced setting for Object Ownership until you migrate these ACL permissions to a bucket policy and reset your bucket ACL to the default private ACL. For more information, see [Prerequisites for disabling ACLs](#).

This example bucket ACL grants public read access:

```
{  
    "Owner": {  
        "ID": "852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID"  
    },  
    "Grants": [  
        {  
            "Grantee": {  
                "ID": "  
852b113e7a2f25102679df27bb0ae12b3f85be6BucketOwnerCanonicalUserID",  
                "Type": "CanonicalUser"  
            },  
            "Permission": "FULL_CONTROL"  
        },  
        {  
            "Grantee": {  
                "Type": "Group",  
                "URI": "http://acs.amazonaws.com/groups/global/AllUsers"  
            },  
            "Permission": "READ"  
        }  
    ]  
}
```

The following example `put-bucket-ownership-controls` AWS CLI command applies the Bucket owner enforced setting for Object Ownership:

```
aws s3api put-bucket-ownership-controls --bucket amzn-s3-demo-bucket --ownership-controls Rules=[{ObjectOwnership=BucketOwnerEnforced}]
```

Because the bucket ACL grants public read access, the request fails and returns the following error code:

An error occurred (InvalidBucketAclWithObjectOwnership) when calling the PutBucketOwnershipControls operation: Bucket cannot have ACLs set with ObjectOwnership's BucketOwnerEnforced setting

Security in Amazon S3

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

Security of the cloud

AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to Amazon S3, see [AWS Services in Scope by Compliance Program](#).

Security in the cloud

Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations. For Amazon S3, your responsibility includes the following areas:

- Managing your data, including [object ownership](#) and [encryption](#).
- Classifying your assets.
- [Managing access](#) to your data using [IAM roles](#) and other service configurations to apply the appropriate permissions.
- Enabling detective controls such as [AWS CloudTrail](#) or [Amazon GuardDuty](#) for Amazon S3.

This documentation will help you understand how to apply the shared responsibility model when using Amazon S3. The following topics show you how to configure Amazon S3 to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you monitor and secure your Amazon S3 resources.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Security best practices for Amazon S3

Amazon S3 provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful recommendations rather than prescriptions.

Topics

- [Amazon S3 security best practices](#)
- [Amazon S3 monitoring and auditing best practices](#)
- [Monitoring data security with managed AWS security services](#)

Amazon S3 security best practices

The following best practices for Amazon S3 can help prevent security incidents.

Disable access control lists (ACLs)

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to control ownership of objects uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to data exclusively using access management policies.

A majority of modern use cases in Amazon S3 no longer require the use of [access control lists \(ACLs\)](#). We recommend that you disable ACLs, except in unusual circumstances where you must control access for each object individually. To disable ACLs and take ownership of every object in your bucket, apply the bucket owner enforced setting for S3 Object Ownership. When you disable ACLs, you can easily maintain a bucket with objects uploaded by different AWS accounts.

When ACLs are disabled access control for your data is based on policies, such as the following:

- AWS Identity and Access Management (IAM) user policies
- S3 bucket policies
- Virtual private cloud (VPC) endpoint policies
- AWS Organizations service control policies (SCPs)

- AWS Organizations resource control policies (RCPs)

Disabling ACLs simplifies permissions management and auditing. ACLs are disabled for new buckets by default. You can also disable ACLs for existing buckets. If you have an existing bucket that already has objects in it, after you disable ACLs, the object and bucket ACLs are no longer part of the access-evaluation process. Instead, access is granted or denied on the basis of policies.

Before you disable ACLs, make sure that you do the following:

- Review your bucket policy to ensure that it covers all the ways that you intend to grant access to your bucket outside of your account.
- Reset your bucket ACL to the default (full control to the bucket owner).

After you disable ACLs, the following behaviors occur:

- Your bucket accepts only PUT requests that do not specify an ACL or PUT requests with bucket owner full control ACLs. These ACLs include the `bucket-owner-full-control` canned ACL or equivalent forms of this ACL that are expressed in XML.
- Existing applications that support bucket owner full control ACLs see no impact.
- PUT requests that contain other ACLs (for example, custom grants to certain AWS accounts) fail and return an HTTP status code `400` (Bad Request) with the error code `AccessControlListNotSupported`.

For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Ensure that your Amazon S3 buckets use the correct policies and are not publicly accessible

Unless you explicitly require anyone on the internet to be able to read or write to your S3 bucket, make sure that your S3 bucket is not public. The following are some of the steps that you can take to block public access:

- Use S3 Block Public Access. With S3 Block Public Access, you can easily set up centralized controls to limit public access to your Amazon S3 resources. These centralized controls are enforced regardless of how the resources are created. For more information, see [Blocking public access to your Amazon S3 storage](#).
- Identify Amazon S3 bucket policies that allow a wildcard identity such as "Principal": "`*`" (which effectively means "anyone"). Also look for policies that allow a wildcard action "`*`" (which effectively allows the user to perform any action in the Amazon S3 bucket).

- Similarly, look for Amazon S3 bucket access control lists (ACLs) that provide read, write, or full-access to "Everyone" or "Any authenticated AWS user."
- Use the `ListBuckets` API operation to scan all of your Amazon S3 buckets. Then use `GetBucketAcl`, `GetBucketWebsite`, and `GetBucketPolicy` to determine whether each bucket has compliant access controls and a compliant configuration.
- Use [AWS Trusted Advisor](#) to inspect your Amazon S3 implementation.
- Consider implementing ongoing detective controls by using the [`s3-bucket-public-read-prohibited`](#) and [`s3-bucket-public-write-prohibited`](#) managed AWS Config Rules.

For more information, see [Identity and Access Management for Amazon S3](#).

Implement least privilege access

When granting permissions, you decide who is getting what permissions to which Amazon S3 resources. You enable specific actions that you want to allow on those resources. Therefore, we recommend that you grant only the permissions that are required to perform a task. Implementing least privilege access is fundamental in reducing security risk and the impact that could result from errors or malicious intent.

The following tools are available to implement least privilege access:

- [Policy actions for Amazon S3](#) and [Permissions Boundaries for IAM Entities](#)
- [How Amazon S3 works with IAM](#)
- [Access control list \(ACL\) overview](#)

For guidance on what to consider when choosing one or more of the preceding mechanisms, see [Identity and Access Management for Amazon S3](#).

Use IAM roles for applications and AWS services that require Amazon S3 access

In order for applications running on Amazon EC2 or other AWS services to access Amazon S3 resources, they must include valid AWS credentials in their AWS API requests. We recommend not storing AWS credentials directly in the application or Amazon EC2 instance. These are long-term credentials that are not automatically rotated and could have a significant business impact if they are compromised.

Instead, use an IAM role to manage temporary credentials for applications or services that need to access Amazon S3. When you use a role, you don't have to distribute long-term credentials (such as a username and password or access keys) to an Amazon EC2 instance or AWS service,

such as AWS Lambda. The role supplies temporary permissions that applications can use when they make calls to other AWS resources.

For more information, see the following topics in the *IAM User Guide*:

- [IAM Roles](#)
- [Common Scenarios for Roles: Users, Applications, and Services](#)

Consider encryption of data at rest

You have the following options for protecting data at rest in Amazon S3:

- **Server-side encryption** – All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

Amazon S3 also provides these server-side encryption options:

- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information, see [Protecting data with server-side encryption](#).

- **Client-side encryption** – Encrypt data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, the encryption keys, and related tools. As with server-side encryption, client-side encryption can help reduce risk by encrypting the data with a key that is stored in a different mechanism than the mechanism that stores the data itself.

Amazon S3 provides multiple client-side encryption options. For more information, see [Protecting data by using client-side encryption](#).

Enforce encryption of data in transit

You can use HTTPS (TLS) to help prevent potential attackers from eavesdropping on or manipulating network traffic by using person-in-the-middle or similar attacks. We recommend allowing only encrypted connections over HTTPS (TLS) by using the [aws:SecureTransport](#)

condition in your Amazon S3 bucket policies. For more information, see the example S3 bucket policy [Managing access based on HTTP or HTTPS requests](#). In addition to denying HTTP requests, we recommend that you set Amazon CloudWatch alarms on `tlsDetails.tlsVersion NOT EXISTS` that alert you if HTTP access attempts are made on your content. For more information on how to configure Amazon CloudWatch alarms, see [Creating CloudWatch alarms for CloudTrail events: examples](#) and [CloudTrail record contents](#) in the *AWS CloudTrail User Guide*.

Important

We recommend that your application not pin Amazon S3 TLS certificates as AWS doesn't support pinning of publicly-trusted certificates. S3 automatically renews certificates and renewal can happen any time before certificate expiry. Renewing a certificate generates a new public-private key pair. If you've pinned an S3 certificate which has been recently renewed with a new public key, you won't be able to connect to S3 until your application uses the new certificate.

Also consider implementing ongoing detective controls by using the [s3-bucket-ssl-requests-only](#) managed AWS Config rule.

Consider using S3 Object Lock

With S3 Object Lock, you can store objects by using a "Write Once Read Many" (WORM) model. S3 Object Lock can help prevent accidental or inappropriate deletion of data. For example, you can use S3 Object Lock to help protect your AWS CloudTrail logs.

For more information, see [Locking objects with Object Lock](#).

Enable S3 Versioning

S3 Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your bucket. With versioning, you can easily recover from both unintended user actions and application failures.

Also consider implementing ongoing detective controls by using the [s3-bucket-versioning-enabled](#) managed AWS Config rule.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Consider using S3 Cross-Region Replication

Although Amazon S3 stores your data across multiple geographically diverse Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. With S3 Cross-Region Replication (CRR), you can replicate data between distant AWS Regions to help satisfy these requirements. CRR enables automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see [Replicating objects within and across Regions](#).

 **Note**

CRR requires both the source and destination S3 buckets to have versioning enabled.

Also consider implementing ongoing detective controls by using the [s3-bucket-replication-enabled](#) managed AWS Config rule.

Consider using VPC endpoints for Amazon S3 access

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. VPC endpoints can help prevent traffic from traversing the open internet.

VPC endpoints for Amazon S3 provide multiple ways to control access to your Amazon S3 data:

- You can control the requests, users, or groups that are allowed through a specific VPC endpoint by using S3 bucket policies.
- You can control which VPCs or VPC endpoints have access to your S3 buckets by using S3 bucket policies.
- You can help prevent data exfiltration by using a VPC that does not have an internet gateway.

For more information, see [Controlling access from VPC endpoints with bucket policies](#).

Use managed AWS security services to monitor data security

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. These services can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of accounts.

For more information, see [Monitoring data security with managed AWS security services](#).

Amazon S3 monitoring and auditing best practices

The following best practices for Amazon S3 can help detect potential security weaknesses and incidents.

Identify and audit all of your Amazon S3 buckets

Identification of your IT assets is a crucial aspect of governance and security. You need to have visibility of all your Amazon S3 resources to assess their security posture and take action on potential areas of weakness. To audit your resources, we recommend doing the following:

- Use Tag Editor to identify and tag security-sensitive or audit-sensitive resources, then use those tags when you need to search for these resources. For more information, see [Searching for Resources to Tag](#) in the *Tagging AWS Resources User Guide*.
- Use S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).
- Create resource groups for your Amazon S3 resources. For more information, see [What are resource groups?](#) in the *AWS Resource Groups User Guide*.

Implement monitoring by using AWS monitoring tools

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Amazon S3 and your AWS solutions. AWS provides several tools and services to help you monitor Amazon S3 and your other AWS services. For example, you can monitor Amazon CloudWatch metrics for Amazon S3, particularly the PutRequests, GetRequests, 4xxErrors, and DeleteRequests metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#) and [Logging and monitoring in Amazon S3](#).

For a second example, see [Example: Amazon S3 Bucket Activity](#). This example describes how to create a CloudWatch alarm that is triggered when an Amazon S3 API call is made to PUT or DELETE a bucket policy, a bucket lifecycle, or a bucket replication configuration, or to PUT a bucket ACL.

Enable Amazon S3 server access logging

Server access logging provides detailed records of the requests that are made to a bucket. Server access logs can assist you in security and access audits, help you learn about your customer base, and understand your Amazon S3 bill. For instructions on enabling server access logging, see [Logging requests with server access logging](#).

Also consider implementing ongoing detective controls by using the [s3-bucket-logging-enabled](#) AWS Config managed rule.

Use AWS CloudTrail

AWS CloudTrail provides a record of actions taken by a user, a role, or an AWS service in Amazon S3. You can use information collected by CloudTrail to determine the following:

- The request that was made to Amazon S3
- The IP address from which the request was made
- Who made the request
- When the request was made
- Additional details about the request

For example, you can identify CloudTrail entries for PUT actions that affect data access, in particular PutBucketAcl, PutObjectAcl, PutBucketPolicy, and PutBucketWebsite.

When you set up your AWS account, CloudTrail is enabled by default. You can view recent events in the CloudTrail console. To create an ongoing record of activity and events for your Amazon S3 buckets, you can create a trail in the CloudTrail console. For more information, see [Logging data events](#) in the *AWS CloudTrail User Guide*.

When you create a trail, you can configure CloudTrail to log data events. Data events are records of resource operations performed on or within a resource. In Amazon S3, data events record object-level API activity for individual buckets. CloudTrail supports a subset of Amazon S3 object-level API operations, such as GetObject, DeleteObject, and PutObject. For more information about how CloudTrail works with Amazon S3, see [Logging Amazon S3 API calls using AWS CloudTrail](#). In the Amazon S3 console, you can also configure your S3 buckets to [Enabling CloudTrail event logging for S3 buckets and objects](#).

AWS Config provides a managed rule (`cloudtrail-s3-dataevents-enabled`) that you can use to confirm that at least one CloudTrail trail is logging data events for your S3 buckets. For more information, see [cloudtrail-s3-dataevents-enabled](#) in the *AWS Config Developer Guide*.

Enable AWS Config

Several of the best practices listed in this topic suggest creating AWS Config rules. AWS Config helps you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config monitors resource configurations so that you can evaluate the recorded configurations against the desired secure configurations. With AWS Config, you can do the following:

- Review changes in configurations and relationships between AWS resources
- Investigate detailed resource-configuration histories
- Determine your overall compliance against the configurations specified in your internal guidelines

Using AWS Config can help you simplify compliance auditing, security analysis, change management, and operational troubleshooting. For more information, see [Setting Up AWS Config with the Console](#) in the *AWS Config Developer Guide*. When specifying the resource types to record, ensure that you include Amazon S3 resources.

 **Important**

AWS Config managed rules only supports general purpose buckets when evaluating Amazon S3 resources. AWS Config doesn't record configuration changes for directory buckets. For more information, see [AWS Config Managed Rules](#) and [List of AWS Config Managed Rules](#) in the *AWS Config Developer Guide*.

For an example of how to use AWS Config, see [How to Use AWS Config to Monitor for and Respond to Amazon S3 Buckets Allowing Public Access](#) on the *AWS Security Blog*.

Use S3 Storage Lens

S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

With S3 Storage Lens, you can use metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads.

For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. For more information, see [Understanding Amazon S3 Storage Lens](#).

Monitor AWS security advisories

We recommend that you regularly check the security advisories posted in Trusted Advisor for your AWS account. In particular, look for warnings about Amazon S3 buckets with "open access permissions." You can do this programmatically by using [describe-trusted-advisor-checks](#).

Further, actively monitor the primary email address that's registered to each of your AWS accounts. AWS uses this email address to contact you about emerging security issues that might affect you.

AWS operational issues with broad impact are posted on the [AWS Health Dashboard - Service health](#). Operational issues are also posted to individual accounts through the AWS Health Dashboard. For more information, see the [AWS Health documentation](#).

Monitoring data security with managed AWS security services

Several managed AWS security services can help you identify, assess, and monitor security and compliance risks for your Amazon S3 data. They can also help you protect your data from those risks. These services include automated detection, monitoring, and protection capabilities that are designed to scale from Amazon S3 resources for a single AWS account to resources for organizations spanning thousands of AWS accounts.

AWS detection and response services can help you identify potential security misconfigurations, threats, or unexpected behaviors, so that you can quickly respond to potentially unauthorized or malicious activity in your environment. AWS data protection services can help you monitor and protect your data, accounts, and workloads from unauthorized access. They can also help you discover sensitive data, such as personally identifiable information (PII), in your Amazon S3 data estate.

To help you identify and evaluate data security and compliance risks, managed AWS security services generate findings to notify you of potential security events or issues with your Amazon S3 data. The findings provide relevant details that you can use to investigate, assess, and act upon these risks according to your incident-response workflows and policies. You can access findings data directly by using each service. You can also send the data to other applications, services, and systems, such as your security incident and event management system (SIEM).

To monitor the security of your Amazon S3 data, consider using these managed AWS security services.

Amazon GuardDuty

Amazon GuardDuty is a threat-detection service that continuously monitors your AWS accounts and workloads for malicious activity and delivers detailed security findings for visibility and remediation.

With the S3 protection feature in GuardDuty, you can configure GuardDuty to analyze AWS CloudTrail management and data events for your Amazon S3 resources. GuardDuty then monitors those events for malicious and suspicious activity. To inform the analysis and identify potential security risks, GuardDuty uses threat-intelligence feeds and machine learning.

GuardDuty can monitor different kinds of activity for your Amazon S3 resources. For example, CloudTrail management events for Amazon S3 include bucket-level operations, such as `ListBuckets`, `DeleteBucket`, and `PutBucketReplication`. CloudTrail data events for Amazon S3 include object-level operations, such as `GetObject`, `ListObjects`, and `PutObject`. If GuardDuty detects anomalous or potentially malicious activity, it generates a finding to notify you.

For more information, see [Amazon S3 Protection in Amazon GuardDuty](#) in the *Amazon GuardDuty User Guide*.

Amazon Detective

Amazon Detective simplifies the investigative process and helps you conduct faster, more effective security investigations. Detective provides prebuilt data aggregations, summaries, and context that can help you analyze and assess the nature and extent of possible security issues.

Detective automatically extracts time-based events, such as API calls from AWS CloudTrail and Amazon VPC Flow Logs for your AWS resources. It also ingests findings generated by Amazon GuardDuty. Detective then uses machine learning, statistical analysis, and graph theory to generate visualizations that help you conduct effective security investigations more quickly.

These visualizations provide a unified, interactive view of resource behaviors and the interactions between them over time. You can explore this behavior graph to examine potentially malicious actions, such as failed login attempts or suspicious API calls. You can also see how these actions affect resources, such as S3 buckets and objects.

For more information, see the [Amazon Detective Administration Guide](#).

IAM Access Analyzer

AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) can help you identify resources that are shared with an external entity. You can also use IAM Access Analyzer to validate IAM policies against policy grammar and best practices, and generate IAM policies based on access activity in your AWS CloudTrail logs.

IAM Access Analyzer uses logic-based reasoning to analyze resource policies in your AWS environment, such as bucket policies. With IAM Access Analyzer for S3, you're alerted when an S3 bucket is configured to allow access to anyone on the internet or other AWS accounts, including accounts outside your organization. For example, IAM Access Analyzer for S3 can report that a bucket has read or write access provided through a bucket access control list (ACL), a bucket policy, a Multi-Region Access Point policy, or an access point policy. For each public or shared bucket, you receive findings that indicate the source and level of public or shared access. With these findings, you can take immediate and precise corrective action to restore bucket access to what you intended.

For more information, see [Reviewing bucket access using IAM Access Analyzer for S3](#).

Amazon Macie

Amazon Macie is a security service that discovers sensitive data by using machine learning and pattern matching. Macie provides visibility into data security risks, and enables automated protection against those risks. With Macie, you can automate the discovery and reporting of sensitive data in your Amazon S3 data estate to gain a better understanding of the data that your organization stores in S3.

To detect sensitive data with Macie, you can use built-in criteria and techniques that are designed to detect a large and growing list of sensitive data types for many countries and regions. These sensitive data types include multiple types of personally identifiable information (PII), financial data, and credentials data. You can also use custom criteria that you define—regular expressions that define text patterns to match and, optionally, character sequences and proximity rules that refine the results.

If Macie detects sensitive data in an S3 object, Macie generates a security finding to notify you. This finding provides information about the affected object, the types and number of occurrences of the sensitive data that Macie found, and additional details to help you investigate the affected S3 bucket and object. For more information, see the [Amazon Macie User Guide](#).

AWS Security Hub

AWS Security Hub is a security-posture management service that performs security best-practice checks, aggregates alerts and findings from multiple sources into a single format, and enables automated remediation.

Security Hub collects and provides security findings data from integrated AWS Partner Network security solutions and AWS services, including Amazon Detective, Amazon GuardDuty, IAM Access Analyzer, and Amazon Macie. It also generates its own findings by running continuous, automated security checks based on AWS best practices and supported industry standards.

Security Hub then correlates and consolidates findings across providers to help you prioritize and process the most significant findings. It also provides support for custom actions, which you can use to invoke responses or remediation actions for specific classes of findings.

With Security Hub, you can assess the security and compliance status of your Amazon S3 resources, and you can do so as part of a broader analysis of your organization's security posture in individual AWS Regions and across multiple Regions. This includes analyzing security trends and identifying the highest-priority security issues. You can also aggregate findings from multiple AWS Regions, and monitor and process aggregated findings data from a single Region.

For more information, see [Amazon Simple Storage Service controls](#) in the *AWS Security Hub User Guide*.

Data protection in Amazon S3

Amazon S3 provides a highly durable storage infrastructure designed for mission-critical and primary data storage. S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive redundantly store objects on multiple devices across a minimum of three Availability Zones in an AWS Region. An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. Availability Zones are physically separated by a meaningful distance, many kilometers, from any other Availability Zone, although all are within 100 km (60 miles) of each other. The S3 One Zone-IA storage class stores data redundantly across multiple devices within a single Availability Zone. These services are designed to handle concurrent device failures by quickly detecting and repairing any lost redundancy, and they also regularly verify the integrity of your data using checksums.

Amazon S3 standard storage offers the following features:

- Backed with the [Amazon S3 Service Level Agreement](#).
- Designed to provide 99.999999999% durability and 99.99% availability of objects over a given year.
- S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive are all designed to sustain data in the event of the loss of an entire Amazon S3 Availability Zone.

Amazon S3 further protects your data using versioning. You can use versioning to preserve, retrieve, and restore every version of every object that is stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. By default, requests retrieve the most recently written version. You can retrieve older versions of an object by specifying a version of the object in a request.

Apart from S3 Versioning, you can also use Amazon S3 Object Lock and S3 Replication to protect your data. For more information, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management, so that each user is given only the permissions necessary to fulfill their job duties.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

The following security best practices also address data protection in Amazon S3:

- [Implement server-side encryption](#)
- [Enforce encryption of data in transit](#)
- [Consider using Macie with Amazon S3](#)
- [Identify and audit all your Amazon S3 buckets](#)
- [Monitor Amazon Web Services security advisories](#)

Protecting data with encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Data protection refers to protecting data while it's in transit (as it travels to and from Amazon S3) and at rest (while it is stored on disks in Amazon S3 data centers). You can protect data in transit by using Secure Socket Layer/Transport Layer Security (SSL/TLS) or client-side encryption. For protecting data at rest in Amazon S3, you have the following options:

- **Server-side encryption** – Amazon S3 encrypts your objects before saving them on disks in AWS data centers and then decrypts the objects when you download them.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

For more information about each option for server-side encryption, see [Protecting data with server-side encryption](#).

To configure server-side encryption, see:

- [Specifying server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#)
 - [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
 - [the section called “Specifying DSSE-KMS”](#)
 - [Specifying server-side encryption with customer-provided keys \(SSE-C\)](#)
- **Client-side encryption** – You encrypt your data client-side and upload the encrypted data to Amazon S3. In this case, you manage the encryption process, encryption keys, and related tools.

To configure client-side encryption, see [Protecting data by using client-side encryption](#).

To see which percentage of your storage bytes are encrypted, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

For more information about server-side encryption and client-side encryption, review the following topics.

Topics

- [Protecting data with server-side encryption](#)
- [Protecting data by using client-side encryption](#)

Protecting data with server-side encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API

response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Server-side encryption is the encryption of data at its destination by the application or service that receives it. Amazon S3 encrypts your data at the object level as it writes it to disks in AWS data centers and decrypts it for you when you access it. As long as you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted objects. For example, if you share your objects by using a presigned URL, that URL works the same way for both encrypted and unencrypted objects. Additionally, when you list objects in your bucket, the list API operations return a list of all objects, regardless of whether they are encrypted.

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

 **Note**

You can't apply different types of server-side encryption to the same object simultaneously.

If you need to encrypt your existing objects, use S3 Batch Operations and S3 Inventory. For more information, see [Encrypting objects with Amazon S3 Batch Operations](#) and [Performing object operations in bulk with Batch Operations](#).

You have four mutually exclusive options for server-side encryption, depending on how you choose to manage the encryption keys and the number of encryption layers that you want to apply.

Server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default. The default option for server-side encryption is with Amazon S3 managed keys (SSE-S3). Each object is encrypted with a unique key. As an additional safeguard, SSE-S3 encrypts the key itself with a root key that it regularly rotates. SSE-S3 uses one of the strongest block ciphers available, 256-bit Advanced Encryption Standard (AES-256), to encrypt your data. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)

Server-side encryption with AWS KMS keys (SSE-KMS) is provided through an integration of the AWS KMS service with Amazon S3. With AWS KMS, you have more control over your keys. For example, you can view separate keys, edit control policies, and follow the keys in AWS CloudTrail. Additionally, you can create and manage customer managed keys or use AWS managed keys that are unique to you, your service, and your Region. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS)

Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) is similar to SSE-KMS, but DSSE-KMS applies two individual layers of object-level encryption instead of one layer. Because both layers of encryption are applied to an object on the server side, you can use a wide range of AWS services and tools to analyze data in S3 while using an encryption method that can satisfy your compliance requirements. For more information, see [Using dual-layer server-side encryption with AWS KMS keys \(DSSE-KMS\)](#).

Server-side encryption with customer-provided keys (SSE-C)

With server-side encryption with customer-provided keys (SSE-C), you manage the encryption keys, and Amazon S3 manages the encryption as it writes to disks and the decryption when you access your objects. For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

Setting default server-side encryption behavior for Amazon S3 buckets

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and

with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

All Amazon S3 buckets have encryption configured by default, and objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption setting applies to all objects in your Amazon S3 buckets.

If you need more control over your keys, such as managing key rotation and access policy grants, you can choose to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about editing KMS keys, see [Editing keys](#) in *AWS Key Management Service Developer Guide*.

Note

We've changed buckets to encrypt new object uploads automatically. If you previously created a bucket without default encryption, Amazon S3 will enable encryption by default for the bucket using SSE-S3. There will be no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or SSE-KMS configured. If you want to encrypt your objects with SSE-KMS, you must change the encryption type in your bucket settings. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

When you configure your bucket to use default encryption with SSE-KMS, you can also enable S3 Bucket Keys to decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of encryption. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To identify buckets that have SSE-KMS enabled for default encryption, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to protect your data](#).

When you use server-side encryption, Amazon S3 encrypts an object before saving it to disk and decrypts it when you download the object. For more information about protecting data using

server-side encryption and encryption-key management, see [Protecting data with server-side encryption](#).

For more information about the permissions required for default encryption, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

You can configure the Amazon S3 default encryption behavior for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Encrypting existing objects

To encrypt your existing unencrypted Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation. You can use the [Batch Operations Copy operation](#) to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and the *AWS Storage Blog* post [Encrypting objects with Amazon S3 Batch Operations](#).

You can also encrypt existing objects by using the `CopyObject` API operation or the `copy-object` AWS CLI command. For more information, see the *AWS Storage Blog* post [Encrypting existing Amazon S3 objects with the AWS CLI](#).

Note

Amazon S3 buckets with default bucket encryption set to SSE-KMS cannot be used as destination buckets for [the section called “Logging server access”](#). Only SSE-S3 default encryption is supported for server access log destination buckets.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (`aws/s3`) is used.
- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (`aws/s3`).

- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted Encrypt permission to. For more information, see [Allow key users to use a KMS key for cryptographic operations](#) in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see [Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?](#)

Using default encryption with replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

For more information about using default encryption with SSE-KMS, see [Replicating encrypted objects](#).

Using Amazon S3 Bucket Keys with default encryption

When you configure your bucket to use SSE-KMS as the default encryption behavior for new objects, you can also configure S3 Bucket Keys. S3 Bucket Keys decrease the number of transactions from Amazon S3 to AWS KMS to reduce the cost of SSE-KMS.

When you configure your bucket to use S3 Bucket Keys for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create a unique [data key](#) for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations.

For more information about using S3 Bucket Keys, see [Using Amazon S3 Bucket Keys](#).

Configuring default encryption

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Amazon S3 buckets have bucket encryption enabled by default, and new objects are automatically encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3). This encryption applies to all new objects in your Amazon S3 buckets, and comes at no cost to you.

If you need more control over your encryption keys, such as managing key rotation and access policy grants, you can elect to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). For more information about SSE-KMS, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#). For more information about DSSE-KMS, see [the section called “Dual-layer server-side encryption \(DSSE-KMS\)”](#).

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

When you set default bucket encryption to SSE-KMS, you can also configure an S3 Bucket Key to reduce your AWS KMS request costs. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

Note

If you use [PutBucketEncryption](#) to set your default bucket encryption to SSE-KMS, you should verify that your KMS key ID is correct. Amazon S3 does not validate the KMS key ID provided in PutBucketEncryption requests.

There are no additional charges for using default encryption for S3 buckets. Requests to configure the default encryption behavior incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#). For SSE-KMS and DSSE-KMS, AWS KMS charges apply and are listed at [AWS KMS pricing](#).

Server-side encryption with customer-provided keys (SSE-C) is not supported for default encryption.

You can configure Amazon S3 default encryption for an S3 bucket by using the Amazon S3 console, the AWS SDKs, the Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI).

Changes to note before enabling default encryption

After you enable default encryption for a bucket, the following encryption behavior applies:

- There is no change to the encryption of the objects that existed in the bucket before default encryption was enabled.
- When you upload objects after enabling default encryption:
 - If your PUT request headers don't include encryption information, Amazon S3 uses the bucket's default encryption settings to encrypt the objects.
 - If your PUT request headers include encryption information, Amazon S3 uses the encryption information from the PUT request to encrypt objects before storing them in Amazon S3.
- If you use the SSE-KMS or DSSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

Note

Objects uploaded before default encryption was enabled will not be encrypted. For information about encrypting existing objects, see [the section called “Setting default bucket encryption”](#).

Using the S3 console

To configure default encryption on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. To configure encryption, under **Encryption type**, choose one of the following:
 - **Server-side encryption with Amazon S3 managed keys (SSE-S3)**
 - **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**
 - **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**

⚠ Important

If you use the SSE-KMS or DSSE-KMS options for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

Buckets and new objects are encrypted by default with SSE-S3, unless you specify another type of default encryption for your buckets. For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about using Amazon S3 server-side encryption to encrypt your data, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

7. If you chose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)** or **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**, do the following:

a. Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

⚠ Important

You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console only lists 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can only see the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter the KMS key ARN.

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 only supports symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

For more information about using SSE-KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). For more information about using DSSE-KMS, see [the section called "Dual-layer server-side encryption \(DSSE-KMS\)"](#).

- b. When you configure your bucket to use default encryption with SSE-KMS, you can also enable an S3 Bucket Key. S3 Bucket Keys lower the cost of encryption by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To use S3 Bucket Keys, under **Bucket Key**, choose **Enable**.

 **Note**

S3 Bucket Keys aren't supported for DSSE-KMS.

8. Choose **Save changes**.

Using the AWS CLI

These examples show you how to configure default encryption by using SSE-S3 or by using SSE-KMS with an S3 Bucket Key.

For more information about default encryption, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about using the AWS CLI to configure default encryption, see [put-bucket-encryption](#).

Example – Default encryption with SSE-S3

This example configures default bucket encryption with Amazon S3 managed keys.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "AES256"  
            }  
        }  
    ]  
}'
```

Example – Default encryption with SSE-KMS using an S3 Bucket Key

This example configures default bucket encryption with SSE-KMS using an S3 Bucket Key.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-configuration '{  
    "Rules": [  
        {  
            "ApplyServerSideEncryptionByDefault": {  
                "SSEAlgorithm": "aws:kms",  
                "KMSMasterKeyID": "KMS-Key-ARN"  
            },  
            "BucketKeyEnabled": true  
        }  
    ]  
}'
```

Using the REST API

Use the REST API PutBucketEncryption operation to enable default encryption and to set the type of server-side encryption to use—SSE-S3, SSE-KMS, or DSSE-KMS.

For more information, see [PutBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

Monitoring default encryption with AWS CloudTrail and Amazon EventBridge

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

You can track default encryption configuration requests for Amazon S3 buckets by using AWS CloudTrail events. The following API event names are used in CloudTrail logs:

- PutBucketEncryption
- GetBucketEncryption

- [DeleteBucketEncryption](#)

You can also create EventBridge rules to match the CloudTrail events for these API calls. For more information about CloudTrail events, see [Enable logging for objects in a bucket using the console](#). For more information about EventBridge events, see [Events from AWS services](#).

You can use CloudTrail logs for object-level Amazon S3 actions to track PUT and POST requests to Amazon S3. You can use these actions to verify whether default encryption is being used to encrypt objects when incoming PUT requests don't have encryption headers.

When Amazon S3 encrypts an object by using the default encryption settings, the log includes one of the following fields as the name-value pair: "SSEApplied": "Default_SSE_S3", "SSEApplied": "Default_SSE_KMS", or "SSEApplied": "Default_DSSE_KMS".

When Amazon S3 encrypts an object by using the PUT encryption headers, the log includes one of the following fields as the name-value pair: "SSEApplied": "SSE_S3", "SSEApplied": "SSE_KMS", "SSEApplied": "DSSE_KMS", or "SSEApplied": "SSE_C".

For multipart uploads, this information is included in your `InitiateMultipartUpload` API operation requests. For more information about using CloudTrail and CloudWatch, see [Logging and monitoring in Amazon S3](#).

Default encryption FAQ

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. SSE-S3, which uses 256-bit Advanced Encryption Standard (AES-256), is automatically applied to all new buckets and to any existing S3 bucket that doesn't already have default encryption configured. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

The following sections answer questions about this update.

Does Amazon S3 change the default encryption settings for my existing buckets that already have default encryption configured?

No. There are no changes to the default encryption configuration for an existing bucket that already has SSE-S3 or server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) configured. For more information about how to set the default encryption behavior for buckets, see [Setting default server-side encryption behavior for Amazon S3 buckets](#). For more information about SSE-S3 and SSE-KMS encryption settings, see [Protecting data with server-side encryption](#).

Is default encryption enabled on my existing buckets that don't have default encryption configured?

Yes. Amazon S3 now configures default encryption on all existing unencrypted buckets to apply server-side encryption with S3 managed keys (SSE-S3) as the base level of encryption for new objects uploaded to these buckets. Objects that are already in an existing unencrypted bucket won't be automatically encrypted.

How can I view the default encryption status of new object uploads?

Currently, you can view the default encryption status of new object uploads in AWS CloudTrail logs, S3 Inventory, and S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs.

- To view your CloudTrail events, see [Viewing CloudTrail events in the CloudTrail console](#) in the *AWS CloudTrail User Guide*. CloudTrail logs provide API tracking for PUT and POST requests to Amazon S3. When default encryption is being used to encrypt objects in your buckets, the CloudTrail logs for PUT and POST API requests will include the following field as the name-value pair: "SSEApplied": "Default_SSE_S3".
- To view the automatic encryption status of new object uploads in S3 Inventory, configure an S3 Inventory report to include the **Encryption** metadata field, and then see the encryption status of each new object in the report. For more information, see [Setting up Amazon S3 Inventory](#).
- To view the automatic encryption status for new object uploads in S3 Storage Lens, configure an S3 Storage Lens dashboard and see the **Encrypted bytes** and **Encrypted object count** metrics in the **Data protection** category of the dashboard. For more information, see [Using the S3 console](#) and [Viewing S3 Storage Lens metrics on the dashboards](#).
- To view the automatic bucket-level encryption status in the Amazon S3 console, check the **Default encryption** of your Amazon S3 buckets in the Amazon S3 console. For more information, see [Configuring default encryption](#).

- To view the automatic encryption status as an additional Amazon S3 API response header in the AWS Command Line Interface (AWS CLI) and the AWS SDKs, check the response header `x-amz-server-side-encryption` when you use object action APIs, such as [PutObject](#) and [GetObject](#).

What do I have to do to take advantage of this change?

You are not required to make any changes to your existing applications. Because default encryption is enabled for all of your buckets, all new objects uploaded to Amazon S3 are automatically encrypted.

Can I disable encryption for the new objects being written to my bucket?

No. SSE-S3 is the new base level of encryption that's applied to all the new objects being uploaded to your bucket. You can no longer disable encryption for new object uploads.

Will my charges be affected?

No. Default encryption with SSE-S3 is available at no additional cost. You will be billed for storage, requests, and other S3 features, as usual. For pricing, see [Amazon S3 pricing](#).

Will Amazon S3 encrypt my existing objects that are unencrypted?

No. Beginning on January 5, 2023, Amazon S3 only automatically encrypts new object uploads. To encrypt existing objects, you can use S3 Batch Operations to create encrypted copies of your objects. These encrypted copies will retain the existing object data and name and will be encrypted by using the encryption keys that you specify. For more details, see [Encrypting objects with Amazon S3 Batch Operations](#) in the [AWS Storage Blog](#).

I did not enable encryption for my buckets before this release. Do I need to change the way that I access objects?

No. Default encryption with SSE-S3 automatically encrypts your data as it's written to Amazon S3 and decrypts it for you when you access it. There is no change in the way that you access objects that are automatically encrypted.

Do I need to change the way that I access my client-side encrypted objects?

No. All client-side encrypted objects that are encrypted before being uploaded into Amazon S3 arrive as encrypted ciphertext objects within Amazon S3. These objects will now have an additional

layer of SSE-S3 encryption. Your workloads that use client-side encrypted objects will not require any changes to your client services or authorization settings.

Note

HashiCorp Terraform users that aren't using an updated version of the AWS Provider might see an unexpected drift after creating new S3 buckets with no customer defined encryption configuration. To avoid this drift, update your Terraform AWS Provider version to one of the following versions: any 4.x release, 3.76.1, or 2.70.4.

Using server-side encryption with Amazon S3 managed keys (SSE-S3)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

All new object uploads to Amazon S3 buckets are encrypted by default with server-side encryption with Amazon S3 managed keys (SSE-S3).

Server-side encryption protects data at rest. Amazon S3 encrypts each object with a unique key. As an additional safeguard, it encrypts the key itself with a key that it rotates regularly. Amazon S3 server-side encryption uses 256-bit Advanced Encryption Standard Galois/Counter Mode (AES-GCM) to encrypt all uploaded objects.

There are no additional fees for using server-side encryption with Amazon S3 managed keys (SSE-S3). However, requests to configure the default encryption feature incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#).

If you require your data uploads to be encrypted using only Amazon S3 managed keys, you can use the following bucket policy. For example, the following bucket policy denies permissions to upload

an object unless the request includes the `x-amz-server-side-encryption` header to request server-side encryption:

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyObjectsThatAreNotSSES3",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-server-side-encryption": "AES256"  
                }  
            }  
        }  
    ]  
}
```

Note

Server-side encryption encrypts only the object data, not the object metadata.

API support for server-side encryption

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

To configure server-side encryption by using the object creation REST APIs, you must provide the `x-amz-server-side-encryption` request header. For information about the REST APIs, see [Using the REST API](#).

The following Amazon S3 APIs support this header:

- **PUT operations** – Specify the request header when uploading data using the PUT API. For more information, see [PUT Object](#).
- **Initiate Multipart Upload** – Specify the header in the initiate request when uploading large objects using the multipart upload API operation. For more information, see [Initiate Multipart Upload](#).
- **COPY operations** – When you copy an object, you have both a source object and a target object. For more information, see [PUT Object - Copy](#).

 **Note**

When using a POST operation to upload an object, instead of providing the request header, you provide the same information in the form fields. For more information, see [POST Object](#).

The AWS SDKs also provide wrapper APIs that you can use to request server-side encryption. You can also use the AWS Management Console to upload objects and request server-side encryption.

For more general information, see [AWS KMS concepts](#) in the *AWS Key Management Service Developer Guide*.

Topics

- [Specifying server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#)

Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to

use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

You can specify SSE-S3 by using the S3 console, REST APIs, AWS SDKs, and AWS Command Line Interface (AWS CLI). For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

Using the S3 console

This topic describes how to set or change the type of encryption an object by using the AWS Management Console. When you copy an object by using the console, Amazon S3 copies the object as is. That means that if the source object is encrypted, the target object is also encrypted. You can use the console to add or change encryption for an object.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.
- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - Under **Encryption type**, choose **Server-side encryption with Amazon S3 managed keys (SSE-S3)**. SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).
8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

 **Note**

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

At the time of object creation—that is, when you are uploading a new object or making a copy of an existing object—you can specify if you want Amazon S3 to encrypt your data with Amazon S3 managed keys (SSE-S3) by adding the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm AES256, which Amazon S3 supports. Amazon S3 confirms that your object is stored with SSE-S3 by returning the response header `x-amz-server-side-encryption`.

The following REST upload API operations accept the `x-amz-server-side-encryption` request header.

- [PUT Object](#)
- [PUT Object - Copy](#)
- [POST Object](#)
- [Initiate Multipart Upload](#)

When uploading large objects by using the multipart upload API operation, you can specify server-side encryption by adding the `x-amz-server-side-encryption` header to the Initiate Multipart Upload request. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored using SSE-S3.

- [PUT Object](#)
- [PUT Object - Copy](#)
- [POST Object](#)
- [Initiate Multipart Upload](#)
- [Upload Part](#)
- [Upload Part - Copy](#)
- [Complete Multipart Upload](#)
- [Get Object](#)
- [Head Object](#)

 **Note**

Do not send encryption request headers for GET requests and HEAD requests if your object uses SSE-S3, or you'll get an HTTP status code 400 (Bad Request) error.

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use server-side encryption with Amazon S3 managed encryption keys (SSE-S3). This section provides examples of using the AWS SDKs in multiple languages. For information about other SDKs, go to [Sample Code and Libraries](#).

Java

When you use the AWS SDK for Java to upload an object, you can use SSE-S3 to encrypt it. To request server-side encryption, use the `ObjectMetadata` property of the `PutObjectRequest` to set the `x-amz-server-side-encryption` request header. When you call the `putObject()` method of the `AmazonS3Client`, Amazon S3 encrypts and saves the data.

You can also request SSE-S3 encryption when uploading objects with the multipart upload API operation:

- When using the high-level multipart upload API operation, you use the `TransferManager` methods to apply server-side encryption to objects as you upload them. You can use any of the upload methods that take `ObjectMetadata` as a parameter. For more information, see [Uploading an object using multipart upload](#).
- When using the low-level multipart upload API operation, you specify server-side encryption when you initiate the multipart upload. You add the `ObjectMetadata` property by calling the `InitiateMultipartUploadRequest.setObjectMetadata()` method. For more information, see [Using the AWS SDKs \(low-level API\)](#).

You can't directly change the encryption state of an object (encrypting an unencrypted object or decrypting an encrypted object). To change an object's encryption state, you make a copy of the object, specifying the desired encryption state for the copy, and then delete the original object. Amazon S3 encrypts the copied object only if you explicitly request server-side encryption. To request encryption of the copied object through the Java API, use the `ObjectMetadata` property to specify server-side encryption in the `CopyObjectRequest`.

Example Example

The following example shows how to set server-side encryption by using the AWS SDK for Java. It shows how to perform the following tasks:

- Upload a new object by using SSE-S3.

- Change an object's encryption state (in this example, encrypting a previously unencrypted object) by making a copy of the object.
- Check the encryption state of the object.

For more information about server-side encryption, see [Using the REST API](#). For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

        String keyNameToCopyAndEncrypt = "*** Key name for an unencrypted object to be encrypted by copying ***";
        String copiedObjectKeyName = "*** Key name for the encrypted copy of the unencrypted object ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withRegion(clientRegion)
                .withCredentials(new ProfileCredentialsProvider())
                .build();

            // Upload an object and encrypt it with SSE.
            uploadObjectWithSSEEncryption(s3Client, bucketName, keyNameToEncrypt);

            // Upload a new unencrypted object, then change its encryption state
        }
    }
}
```

```
// to encrypted by making a copy.
changeSSEEncryptionStatusByCopying(s3Client,
    bucketName,
    keyNameToCopyAndEncrypt,
    copiedObjectKeyName);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}

private static void uploadObjectWithSSEEncryption(AmazonS3 s3Client, String
bucketName, String keyName) {
    String objectContent = "Test object encrypted with SSE";
    byte[] objectBytes = objectContent.getBytes();

    // Specify server-side encryption.
    ObjectMetadata objectMetadata = new ObjectMetadata();
    objectMetadata.setContentLength(objectBytes.length);

    objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
    PutObjectRequest putRequest = new PutObjectRequest(bucketName,
        keyName,
        new ByteArrayInputStream(objectBytes),
        objectMetadata);

    // Upload the object and check its encryption status.
    PutObjectResult putResult = s3Client.putObject(putRequest);
    System.out.println("Object \\" + keyName + "\\" uploaded with SSE.");
    printEncryptionStatus(putResult);
}

private static void changeSSEEncryptionStatusByCopying(AmazonS3 s3Client,
    String bucketName,
    String sourceKey,
    String destKey) {
    // Upload a new, unencrypted object.
    PutObjectResult putResult = s3Client.putObject(bucketName, sourceKey,
    "Object example to encrypt by copying");
```

```
System.out.println("Unencrypted object \\" + sourceKey + "\\" uploaded.");
printEncryptionStatus(putResult);

// Make a copy of the object and use server-side encryption when storing the
// copy.
CopyObjectRequest request = new CopyObjectRequest(bucketName,
    sourceKey,
    bucketName,
    destKey);
ObjectMetadata objectMetadata = new ObjectMetadata();

objectMetadata.setSSEAlgorithm(ObjectMetadata.AES_256_SERVER_SIDE_ENCRYPTION);
request.setNewObjectMetadata(objectMetadata);

// Perform the copy operation and display the copy's encryption status.
CopyObjectResult response = s3Client.copyObject(request);
System.out.println("Object \\" + destKey + "\\" uploaded with SSE.");
printEncryptionStatus(response);

// Delete the original, unencrypted object, leaving only the encrypted copy
in
// Amazon S3.
s3Client.deleteObject(bucketName, sourceKey);
System.out.println("Unencrypted object \\" + sourceKey + "\\" deleted.");
}

private static void printEncryptionStatus(SSEResultBase response) {
    String encryptionStatus = response.getSSEAlgorithm();
    if (encryptionStatus == null) {
        encryptionStatus = "Not encrypted with SSE";
    }
    System.out.println("Object encryption status is: " + encryptionStatus);
}
}
```

.NET

When you upload an object, you can direct Amazon S3 to encrypt it. To change the encryption state of an existing object, you make a copy of the object and delete the source object. By default, the copy operation encrypts the target only if you explicitly request server-side encryption of the target object. To specify SSE-S3 in the `CopyObjectRequest`, add the following:

```
ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
```

For a working sample of how to copy an object, see [Using the AWS SDKs](#).

The following example uploads an object. In the request, the example directs Amazon S3 to encrypt the object. The example then retrieves object metadata and verifies the encryption method that was used. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SpecifyServerSideEncryptionTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string keyName = "*** key name for object created ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            WritingAnObjectAsync().Wait();
        }

        static async Task WritingAnObjectAsync()
        {
            try
            {
                var putRequest = new PutObjectRequest
                {
                    BucketName = bucketName,
                    Key = keyName,
                    ContentBody = "sample text",
                    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AES256
                };
            }
        }
    }
}
```

```
};

    var putResponse = await client.PutObjectAsync(putRequest);

    // Determine the encryption state of an object.
    GetObjectMetadataRequest metadataRequest = new
GetObjectMetadataRequest
{
    BucketName = bucketName,
    Key = keyName
};
    GetObjectMetadataResponse response = await
client.GetObjectMetadataAsync(metadataRequest);
    ServerSideEncryptionMethod objectEncryption =
response.ServerSideEncryptionMethod;

    Console.WriteLine("Encryption method used: {0}",
objectEncryption.ToString());
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered ***. Message:'{0}' when writing
an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}

}

}
```

PHP

This topic shows how to use classes from version 3 of the AWS SDK for PHP to add SSE-S3 to objects that you upload to Amazon S3. For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

To upload an object to Amazon S3, use the [Aws\S3\S3Client::putObject\(\)](#) method. To add the x-amz-server-side-encryption request header to your upload request, specify the ServerSideEncryption parameter with the value AES256, as shown in the following code example. For information about server-side encryption requests, see [Using the REST API](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

// $filepath should be an absolute path to a file on disk.
$filepath = '*** Your File Path ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Upload a file with server-side encryption.
$result = $s3->putObject([
    'Bucket'           => $bucket,
    'Key'              => $keyname,
    'SourceFile'       => $filepath,
    'ServerSideEncryption' => 'AES256',
]);

```

In response, Amazon S3 returns the `x-amz-server-side-encryption` header with the value of the encryption algorithm that was used to encrypt your object's data.

When you upload large objects by using the multipart upload API operation, you can specify SSE-S3 for the objects that you are uploading, as follows:

- When you're using the low-level multipart upload API operation, specify server-side encryption when you call the [Aws\S3\S3Client::createMultipartUpload\(\)](#) method. To add the `x-amz-server-side-encryption` request header to your request, specify the array parameter's `ServerSideEncryption` key with the value AES256. For more information about the low-level multipart upload API operation, see [Using the AWS SDKs \(low-level API\)](#).
- When you're using the high-level multipart upload API operation, specify server-side encryption by using the `ServerSideEncryption` parameter of the [CreateMultipartUpload](#) API operation. For an example of using the `setOption()` method with the high-level multipart upload API operation, see [Uploading an object using multipart upload](#).

To determine the encryption state of an existing object, retrieve the object metadata by calling the [Aws\S3\S3Client::headObject\(\)](#) method as shown in the following PHP code example.

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';
$keyname = '*** Your Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Check which server-side encryption algorithm is used.
$result = $s3->headObject([
    'Bucket' => $bucket,
    'Key'     => $keyname,
]);
echo $result['ServerSideEncryption'];
```

To change the encryption state of an existing object, make a copy of the object by using the [Aws\S3\S3Client::copyObject\(\)](#) method and delete the source object. By default, `copyObject()` does not encrypt the target unless you explicitly request server-side encryption of the destination object by using the `ServerSideEncryption` parameter with the value `AES256`. The following PHP code example makes a copy of an object and adds server-side encryption to the copied object.

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$sourceBucket = '*** Your Source Bucket Name ***';
$sourceKeyname = '*** Your Source Object Key ***';

$targetBucket = '*** Your Target Bucket Name ***';
$targetKeyname = '*** Your Target Object Key ***';

$s3 = new S3Client([
    'version' => 'latest',
```

```
'region' => 'us-east-1'  
]);  
  
// Copy an object and add server-side encryption.  
$s3->copyObject([  
    'Bucket'          => $targetBucket,  
    'Key'             => $targetKeyname,  
    'CopySource'      => "$sourceBucket/$sourceKeyname",  
    'ServerSideEncryption' => 'AES256',  
]);
```

For more information, see the following topics:

- [AWS SDK for PHP for Amazon S3 Aws\S3\S3Client Class](#)
- [AWS SDK for PHP Documentation](#)

Ruby

When using the AWS SDK for Ruby to upload an object, you can specify that the object be stored encrypted at rest with SSE-S3. When you read the object back, it is automatically decrypted.

The following AWS SDK for Ruby Version 3 example demonstrates how to specify that a file uploaded to Amazon S3 be encrypted at rest.

```
require 'aws-sdk-s3'  
  
# Wraps Amazon S3 object actions.  
class ObjectPutSseWrapper  
    attr_reader :object  
  
    # @param object [Aws::S3::Object] An existing Amazon S3 object.  
    def initialize(object)  
        @object = object  
    end  
  
    def put_object_encrypted(object_content, encryption)  
        @object.put(body: object_content, server_side_encryption: encryption)  
        true  
    rescue Aws::Errors::ServiceError => e  
        puts "Couldn't put your content to #{object.key}. Here's why: #{e.message}"  
    end
```

```
    false
  end
end

# Example usage:
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-encrypted-content"
  object_content = "This is my super-secret content."
  encryption = "AES256"

  wrapper = ObjectPutSseWrapper.new(Aws::S3::Object.new(bucket_name,
  object_content))
  return unless wrapper.put_object_encrypted(object_content, encryption)

  puts "Put your content into #{bucket_name}:#{object_key} and encrypted it with
  #{encryption}."
end

run_demo if $PROGRAM_NAME == __FILE__
```

The following code example demonstrates how to determine the encryption state of an existing object.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectGetEncryptionWrapper
  attr_reader :object

  # @param object [Aws::S3::Object] An existing Amazon S3 object.
  def initialize(object)
    @object = object
  end

  # Gets the object into memory.
  #
  # @return [Aws::S3::Types::GetObjectOutput, nil] The retrieved object data if
  # successful; otherwise nil.
  def object
    @object.get
  rescue Aws::Errors::ServiceError => e
    puts "Couldn't get object #{@object.key}. Here's why: #{e.message}"
  end
end
```

```
end
end

# Example usage:
def run_demo
  bucket_name = "amzn-s3-demo-bucket"
  object_key = "my-object.txt"

  wrapper = ObjectGetEncryptionWrapper.new(Aws::S3::Object.new(bucket_name,
object_key))
  obj_data = wrapper.get_object
  return unless obj_data

  encryption = obj_data.server_side_encryption.nil? ? 'no' :
obj_data.server_side_encryption
  puts "Object #{object_key} uses #{encryption} encryption."
end

run_demo if $PROGRAM_NAME == __FILE__
```

If server-side encryption is not used for the object that is stored in Amazon S3, the method returns null.

To change the encryption state of an existing object, make a copy of the object and delete the source object. By default, the copy methods do not encrypt the target unless you explicitly request server-side encryption. You can request the encryption of the target object by specifying the `server_side_encryption` value in the option's hash argument, as shown in the following Ruby code example. The code example demonstrates how to copy an object and encrypt the copy with SSE-S3.

```
require 'aws-sdk-s3'

# Wraps Amazon S3 object actions.
class ObjectCopyEncryptWrapper
  attr_reader :source_object

  # @param source_object [Aws::S3::Object] An existing Amazon S3 object. This is
  used as the source object for
  #                                         copy actions.
  def initialize(source_object)
    @source_object = source_object
  end
```

```
# Copy the source object to the specified target bucket, rename it with the target
key, and encrypt it.
#
# @param target_bucket [Aws::S3::Bucket] An existing Amazon S3 bucket where the
object is copied.
# @param target_object_key [String] The key to give the copy of the object.
# @return [Aws::S3::Object, nil] The copied object when successful; otherwise,
nil.
def copy_object(target_bucket, target_object_key, encryption)
  @source_object.copy_to(bucket: target_bucket.name, key: target_object_key,
server_side_encryption: encryption)
  target_bucket.object(target_object_key)
rescue Aws::Errors::ServiceError => e
  puts "Couldn't copy #{@source_object.key} to #{target_object_key}. Here's why:
#{e.message}"
end
end

# Example usage:
def run_demo
  source_bucket_name = "amzn-s3-demo-bucket1"
  source_key = "my-source-file.txt"
  target_bucket_name = "amzn-s3-demo-bucket2"
  target_key = "my-target-file.txt"
  target_encryption = "AES256"

  source_bucket = Aws::S3::Bucket.new(source_bucket_name)
  wrapper = ObjectCopyEncryptWrapper.new(source_bucket.object(source_key))
  target_bucket = Aws::S3::Bucket.new(target_bucket_name)
  target_object = wrapper.copy_object(target_bucket, target_key, target_encryption)
  return unless target_object

  puts "Copied #{source_key} from #{source_bucket_name} to
#{target_object.bucket_name}:#{target_object.key} and \"\
    encrypted the target with #{target_object.server_side_encryption}
  encryption.\""
end

run_demo if $PROGRAM_NAME == __FILE__
```

Using the AWS CLI

To specify SSE-S3 when you upload an object by using the AWS CLI, use the following example.

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key object-key-name --server-side-  
encryption AES256 --body file path
```

For more information, see [put-object](#) in the AWS CLI reference. To specify SSE-S3 when you copy an object by using the AWS CLI, see [copy-object](#).

Using AWS CloudFormation

For examples of setting up encryption using AWS CloudFormation, see [Create a bucket with default encryption](#) and the [Create a bucket by using AWS KMS server-side encryption with an S3 Bucket Key](#) example in the AWS ::S3::Bucket ServerSideEncryptionRule topic in the *AWS CloudFormation User Guide*.

Using server-side encryption with AWS KMS keys (SSE-KMS)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Server-side encryption is the encryption of data at its destination by the application or service that receives it.

Amazon S3 automatically enables server-side encryption with Amazon S3 managed keys (SSE-S3) for new object uploads.

Unless you specify otherwise, buckets use SSE-S3 by default to encrypt objects. However, you can choose to configure buckets to use server-side encryption with AWS Key Management Service

(AWS KMS) keys (SSE-KMS) instead. For more information, see [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#).

AWS KMS is a service that combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Amazon S3 uses server-side encryption with AWS KMS (SSE-KMS) to encrypt your S3 object data. Also, when SSE-KMS is requested for the object, the S3 checksum (as part of the object's metadata) is stored in encrypted form. For more information about checksum, see [Checking object integrity in Amazon S3](#).

If you use KMS keys, you can use AWS KMS through the [AWS Management Console](#) or the [AWS KMS API](#) to do the following:

- Centrally create, view, edit, monitor, enable or disable, rotate, and schedule deletion of KMS keys.
- Define the policies that control how and by whom KMS keys can be used.
- Audit their usage to prove that they are being used correctly. Auditing is supported by the [AWS KMS API](#), but not by the [AWS KMS AWS Management Console](#).

The security controls in AWS KMS can help you meet encryption-related compliance requirements. You can use these KMS keys to protect your data in Amazon S3 buckets. When you use SSE-KMS encryption with an S3 bucket, the AWS KMS keys must be in the same Region as the bucket.

There are additional charges for using AWS KMS keys. For more information, see [AWS KMS key concepts](#) in the [AWS Key Management Service Developer Guide](#) and [AWS KMS pricing](#).

Permissions

To successfully make a PutObject request to encrypt an object with an AWS KMS key to Amazon S3, you need kms:GenerateDataKey permissions on the key. To download an object encrypted with an AWS KMS key, you need kms:Decrypt permissions for the key. To [perform a multipart upload](#) to encrypt an object with an AWS KMS key, you must have the kms:GenerateDataKey and kms:Decrypt permissions for the key.

Important

Carefully review the permissions that are granted in your KMS key policies. Always restrict customer-managed KMS key policy permissions only to the IAM principals and AWS

services that must access the relevant AWS KMS key action. For more information, see [Key policies in AWS KMS](#).

Topics

- [AWS KMS keys](#)
- [Amazon S3 Bucket Keys](#)
- [Requiring server-side encryption](#)
- [Encryption context](#)
- [Sending requests for AWS KMS encrypted objects](#)
- [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
- [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#)

AWS KMS keys

When you use server-side encryption with AWS KMS (SSE-KMS), you can use the default [AWS managed key](#), or you can specify a [customer managed key](#) that you have already created. AWS KMS supports *envelope encryption*. S3 uses the AWS KMS features for *envelope encryption* to further protect your data. Envelope encryption is the practice of encrypting your plain text data with a data key, and then encrypting that data key with a KMS key. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

If you don't specify a customer managed key, Amazon S3 automatically creates an AWS managed key in your AWS account the first time that you add an object encrypted with SSE-KMS to a bucket. By default, Amazon S3 uses this KMS key for SSE-KMS.

Note

Objects encrypted using SSE-KMS with [AWS managed keys](#) can't be shared cross-account.

If you need to share SSE-KMS data cross-account, you must use a [customer managed key](#) from AWS KMS.

If you want to use a customer managed key for SSE-KMS, create a symmetric encryption customer managed key before you configure SSE-KMS. Then, when you configure SSE-KMS for your bucket,

specify the existing customer managed key. For more information about symmetric encryption key, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

Creating a customer managed key gives you more flexibility and control. For example, you can create, rotate, and disable customer managed keys. You can also define access controls and audit the customer managed key that you use to protect your data. For more information about customer managed and AWS managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

 **Note**

When you use server-side encryption with a customer managed key that's stored in an external key store, unlike standard KMS keys, you are responsible for ensuring the availability and durability of your key material. For more information about external key stores and how they shift the shared responsibility model, see [External key stores](#) in the *AWS Key Management Service Developer Guide*.

Using SSE-KMS encryption for cross-account operations

When using encryption for cross-account operations, be aware of the following:

- If an AWS KMS key Amazon Resource Name (ARN) or alias is not provided at request time or through the bucket's default encryption configuration, the AWS managed key (aws/s3) is used.
- If you're uploading or accessing S3 objects by using AWS Identity and Access Management (IAM) principals that are in the same AWS account as your KMS key, you can use the AWS managed key (aws/s3).
- If you want to grant cross-account access to your S3 objects, use a customer managed key. You can configure the policy of a customer managed key to allow access from another account.
- If you're specifying a customer managed KMS key, we recommend using a fully qualified KMS key ARN. If you use a KMS key alias instead, AWS KMS resolves the key within the requester's account. This behavior can result in data that's encrypted with a KMS key that belongs to the requester, and not the bucket owner.
- You must specify a key that you (the requester) have been granted Encrypt permission to. For more information, see [Allow key users to use a KMS key for cryptographic operations](#) in the *AWS Key Management Service Developer Guide*.

For more information about when to use customer managed keys and AWS managed KMS keys, see [Should I use an AWS managed key or a customer managed key to encrypt my objects in Amazon S3?](#)

SSE-KMS encryption workflow

If you choose to encrypt your data using an AWS managed key or a customer managed key, AWS KMS and Amazon S3 perform the following envelope encryption actions:

1. Amazon S3 requests a plaintext [data key](#) and a copy of the key encrypted under the specified KMS key.
2. AWS KMS generates a data key, encrypts it under the KMS key, and sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 encrypts the data using the data key and removes the plaintext key from memory as soon as possible after use.
4. Amazon S3 stores the encrypted data key as metadata with the encrypted data.

When you request that your data be decrypted, Amazon S3 and AWS KMS perform the following actions:

1. Amazon S3 sends the encrypted data key to AWS KMS in a Decrypt request.
2. AWS KMS decrypts the encrypted data key by using the same KMS key and returns the plaintext data key to Amazon S3.
3. Amazon S3 decrypts the encrypted data, using the plaintext data key, and removes the plaintext data key from memory as soon as possible.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).

Auditing SSE-KMS encryption

To identify requests that specify SSE-KMS, you can use the **All SSE-KMS requests** and **% all SSE-KMS requests** metrics in Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can also use the SSE-KMS enabled bucket count and % SSE-KMS enabled buckets to understand the count of buckets that (SSE-KMS) for [default bucket encryption](#). For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

To audit the usage of your AWS KMS keys for your SSE-KMS encrypted data, you can use AWS CloudTrail logs. You can get insight into your [cryptographic operations](#), such as [GenerateDataKey](#) and [Decrypt](#). CloudTrail supports numerous [attribute values](#) for filtering your search, including event name, user name, and event source.

Amazon S3 Bucket Keys

When you configure server-side encryption using AWS KMS (SSE-KMS), you can configure your buckets to use S3 Bucket Keys for SSE-KMS. Using a bucket-level key for SSE-KMS can reduce your AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS.

When you configure a bucket to use an S3 Bucket Key for SSE-KMS on new objects, AWS KMS generates a bucket-level key that is used to create unique [data keys](#) for objects in the bucket. This S3 Bucket Key is used for a time-limited period within Amazon S3, further reducing the need for Amazon S3 to make requests to AWS KMS to complete encryption operations. For more information about using S3 Bucket Keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

Requiring server-side encryption

To require server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption-aws-kms-key-id` header that requests server-side encryption with SSE-KMS.

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [{  
        "Sid": "DenyObjectsThatAreNotSSEKMS",  
        "Effect": "Deny",  
        "Principal": "*",  
        "Action": "s3:PutObject",  
        "Resource": "arn:aws:s3:::mybucket/*",  
        "Condition": {"StringNotEquals": {"x-amz-server-side-encryption-aws-kms-key-id": ""}}  
    }]  
}
```

```
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
        "Condition": {
            "Null": {
                "s3:x-amz-server-side-encryption-aws-kms-key-id": "true"
            }
        }
    ]
}
```

To require that a particular AWS KMS key be used to encrypt the objects in a bucket, you can use the `s3:x-amz-server-side-encryption-aws-kms-key-id` condition key. To specify the KMS key, you must use a key Amazon Resource Name (ARN) that is in the `arn:aws:kms:region:acct-id:key/key-id` format. AWS Identity and Access Management does not validate if the string for `s3:x-amz-server-side-encryption-aws-kms-key-id` exists.

Note

When you upload an object, you can specify the KMS key by using the `x-amz-server-side-encryption-aws-kms-key-id` header or rely on your [default bucket encryption configuration](#). If your `PutObject` request specifies `aws:kms` in the `x-amz-server-side-encryption` header, but does not specify the `x-amz-server-side-encryption-aws-kms-key-id` header, then Amazon S3 assumes that you want to use the AWS managed key. Regardless, the AWS KMS key ID that Amazon S3 uses for object encryption must match the AWS KMS key ID in the policy, otherwise Amazon S3 denies the request.

For a complete list of Amazon S3 specific condition keys, see [Condition keys for Amazon S3](#) in the *Service Authorization Reference*.

Encryption context

An *encryption context* is a set of key-value pairs that contains additional contextual information about the data. The encryption context is not encrypted. When an encryption context is specified for an encryption operation, Amazon S3 must specify the same encryption context for the

decryption operation. Otherwise, the decryption fails. AWS KMS uses the encryption context as [additional authenticated data \(AAD\)](#) to support [authenticated encryption](#). For more information about the encryption context, see [Encryption context](#) in the *AWS Key Management Service Developer Guide*.

By default, Amazon S3 uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair:

- **If you use SSE-KMS without enabling an S3 Bucket Key**, the object ARN is used as the encryption context.

`arn:aws:s3:::object_ARN`

- **If you use SSE-KMS and enable an S3 Bucket Key**, the bucket ARN is used as the encryption context. For more information about S3 Bucket Keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

`arn:aws:s3:::bucket_ARN`

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header in an [s3:PutObject](#) request. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context. When it processes your PUT request, Amazon S3 appends the default encryption context of `aws:s3:arn` to the one that you provide.

You can use the encryption context to identify and categorize your cryptographic operations. You can also use the default encryption context ARN value to track relevant requests in AWS CloudTrail by viewing which Amazon S3 ARN was used with which encryption key.

In the `requestParameters` field of a CloudTrail log file, the encryption context looks similar to the following one.

```
"encryptionContext": {  
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1/file_name"  
}
```

When you use SSE-KMS with the optional S3 Bucket Keys feature, the encryption context value is the ARN of the bucket.

```
"encryptionContext": {  
    "aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket1"  
}
```

Sending requests for AWS KMS encrypted objects

Important

All GET and PUT requests for AWS KMS encrypted objects must be made using Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Requests must also be signed using valid credentials, such as AWS Signature Version 4 (or AWS Signature Version 2).

AWS Signature Version 4 is the process of adding authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) and [Signature Version 4 signing process](#).

Important

If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests. Otherwise, you'll get an HTTP 400 Bad Request error.

Topics

- [Specifying server-side encryption with AWS KMS \(SSE-KMS\)](#)
- [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#)

Specifying server-side encryption with AWS KMS (SSE-KMS)

All Amazon S3 buckets have encryption configured by default, and all new objects that are uploaded to an S3 bucket are automatically encrypted at rest. Server-side encryption with Amazon S3 managed keys (SSE-S3) is the default encryption configuration for every bucket in Amazon S3. To use a different type of encryption, you can either specify the type of server-side encryption to use in your S3 PUT requests, or you can set the default encryption configuration in the destination bucket.

If you want to specify a different encryption type in your PUT requests, you can use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). If you want to set a different default encryption configuration in the destination bucket, you can use SSE-KMS or DSSE-KMS.

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify SSE-KMS by using the Amazon S3 console, REST API operations, AWS SDKs, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that's owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This topic describes how to set or change the type of encryption of an object to use server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.

- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.

Important

If you use the SSE-KMS option for your default encryption configuration, you are subject to the requests per second (RPS) quotas of AWS KMS. For more information about AWS KMS quotas and how to request a quota increase, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - a. Under **Encryption type**, choose **Server-side encryption with AWS Key Management Service keys (SSE-KMS)**.
 - b. Under **AWS KMS key**, do one of the following to choose your KMS key:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

8. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
9. Choose **Save changes**.

Note

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of server-side encryption with AWS KMS keys (SSE-KMS) to encrypt your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms`. Amazon S3 confirms that your object is stored using SSE-KMS by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`
- `x-amz-server-side-encryption-context`
- `x-amz-server-side-encryption-bucket-key-enabled`

Topics

- [Amazon S3 REST API operations that support SSE-KMS](#)
- [Encryption context \(x-amz-server-side-encryption-context\)](#)
- [AWS KMS key ID \(x-amz-server-side-encryption-aws-kms-key-id\)](#)
- [S3 Bucket Keys \(x-amz-server-side-encryption-aws-bucket-key-enabled\)](#)

Amazon S3 REST API operations that support SSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- [PutObject](#) – When you upload data by using the PUT API operation, you can specify these request headers.

- [CopyObject](#) – When you copy an object, you have both a source object and a target object. When you pass SSE-KMS headers with the CopyObject operation, they're applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object isn't encrypted unless you explicitly request server-side encryption.
- [POST Object](#) – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- [CreateMultipartUpload](#) – When you upload large objects by using the multipart upload API operation, you can specify these headers. You specify these headers in the CreateMultipartUpload request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored by using server-side encryption.

- [PutObject](#)
- [CopyObject](#)
- [POST Object](#)
- [CreateMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)
- [HeadObject](#)

Important

- All GET and PUT requests for an object protected by AWS KMS fail if you don't make these requests by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses SSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 BadRequest error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object or bucket Amazon Resource Name (ARN) as the encryption context pair. If you use SSE-KMS without enabling an S3 Bucket Key, you use the object ARN as your encryption context; for example, `arn:aws:s3:::object_ARN`. However, if you use SSE-KMS and enable an S3 Bucket Key, you use the bucket ARN for your encryption context; for example, `arn:aws:s3:::bucket_ARN`.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context isn't encrypted, make sure it doesn't include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see [Encryption context](#). For general information about the encryption context, see [AWS Key Management Service Concepts - Encryption context](#) in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (aws/s3) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys (x-amz-server-side-encryption-aws-bucket-key-enabled)

You can use the `x-amz-server-side-encryption-aws-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level. S3 Bucket Keys reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

If you specify the `x-amz-server-side-encryption:aws:kms` header but don't provide the `x-amz-server-side-encryption-aws-bucket-key-enabled` header, your object uses the S3 Bucket Key settings for the destination bucket to encrypt your object. For more information, see [Configuring an S3 Bucket Key at the object level](#).

Using the AWS CLI

To use the following example AWS CLI commands, replace the *user input placeholders* with your own information.

When you upload a new object or copy an existing object, you can specify the use of server-side encryption with AWS KMS keys to encrypt your data. To do this, add the `--server-side-encryption aws:kms` header to the request. Use the `--ssekms-key-id` *example-key-id* to add your [customer managed AWS KMS key](#) that you created. If you specify `--server-side-encryption aws:kms`, but don't provide an AWS KMS key ID, Amazon S3 will use an AWS managed key.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms --ssekms-key-id example-key-id --body filepath
```

You can additionally enable or disable Amazon S3 Bucket Keys on your PUT or COPY operations by adding `--bucket-key-enabled` or `--no-bucket-key-enabled`. Amazon S3 Bucket Keys can reduce your AWS KMS request costs by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms --bucket-key-enabled --body filepath
```

You can encrypt an unencrypted object to use SSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --body filepath --bucket amzn-s3-demo-bucket --key example-object-key --sse aws:kms --sse-kms-key-id example-key-id --body filepath
```

Using the AWS SDKs

When using AWS SDKs, you can request Amazon S3 to use AWS KMS keys for server-side encryption. The following examples show how to use SSE-KMS with the AWS SDKs for Java and .NET. For information about other SDKs, see [Sample code and libraries](#) on the AWS Developer Center.

⚠ Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

CopyObject operation

When copying objects, you add the same request properties (`ServerSideEncryptionMethod` and `ServerSideEncryptionKeyManagementServiceKeyId`) to request Amazon S3 to use an AWS KMS key. For more information about copying objects, see [Copying, moving, and renaming objects](#).

PUT operation

Java

When uploading an object by using the AWS SDK for Java, you can request Amazon S3 to use an AWS KMS key by adding the `SSEAwsKeyManagementParams` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,  
    keyName, file).withSSEAwsKeyManagementParams(new SSEAwsKeyManagementParams());
```

In this case, Amazon S3 uses the AWS managed key (aws/s3). For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). You can optionally create a symmetric encryption KMS key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest = new PutObjectRequest(bucketName,  
    keyName, file).withSSEAwsKeyManagementParams(new  
    SSEAwsKeyManagementParams(keyID));
```

For more information about creating customer managed keys, see [Programming the AWS KMS API in the AWS Key Management Service Developer Guide](#).

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects](#).
- For multipart uploads that use the high-level or low-level multipart upload API operations, see [Uploading an object using multipart upload](#).

.NET

When uploading an object by using the AWS SDK for .NET, you can request Amazon S3 to use an AWS KMS key by adding the `ServerSideEncryptionMethod` property as shown in the following request:

```
PutObjectRequest putRequest = new PutObjectRequest
{
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS
};
```

In this case, Amazon S3 uses the AWS managed key. For more information, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#). You can optionally create your own symmetric encryption customer managed key and specify that in the request, as shown in the following example:

```
PutObjectRequest putRequest1 = new PutObjectRequest
{
    BucketName = amzn-s3-demo-bucket,
    Key = keyName,
    // other properties
    ServerSideEncryptionMethod = ServerSideEncryptionMethod.AWSKMS,
    ServerSideEncryptionKeyManagementServiceKeyId = keyId
};
```

For more information about creating customer managed keys, see [Programming the AWS KMS API](#) in the *AWS Key Management Service Developer Guide*.

For working code examples of uploading an object, see the following topics. To use these examples, you must update the code examples and provide encryption information as shown in the preceding code fragment.

- For uploading an object in a single operation, see [Uploading objects](#).
- For multipart uploads that use the high-level or low-level multipart upload API operations, see [Uploading an object using multipart upload](#).

Presigned URLs

Java

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
ClientConfiguration clientConfiguration = new ClientConfiguration();
clientConfiguration.setSignerOverride("AWSS3V4SignerType");
AmazonS3Client s3client = new AmazonS3Client(
    new ProfileCredentialsProvider(), clientConfiguration);
...
```

For a code example, see [Sharing objects with presigned URLs](#).

.NET

When creating a presigned URL for an object that's encrypted with an AWS KMS key, you must explicitly specify Signature Version 4, as shown in the following example:

```
AWSConfigs.S3Config.UseSignatureVersion4 = true;
```

For a code example, see [Sharing objects with presigned URLs](#).

Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys

Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS). Using a bucket-level key for SSE-KMS can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to

AWS KMS. With a few clicks in the AWS Management Console, and without any changes to your client applications, you can configure your bucket to use an S3 Bucket Key for SSE-KMS encryption on new objects.

 **Note**

S3 Bucket Keys aren't supported for dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS).

S3 Bucket Keys for SSE-KMS

Workloads that access millions or billions of objects encrypted with SSE-KMS can generate large volumes of requests to AWS KMS. When you use SSE-KMS to protect your data without an S3 Bucket Key, Amazon S3 uses an individual AWS KMS [data key](#) for every object. In this case, Amazon S3 makes a call to AWS KMS every time a request is made against a KMS-encrypted object. For information about how SSE-KMS works, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

When you configure your bucket to use an S3 Bucket Key for SSE-KMS, AWS generates a short-lived bucket-level key from AWS KMS, then temporarily keeps it in S3. This bucket-level key will create data keys for new objects during its lifecycle. S3 Bucket Keys are used for a limited time period within Amazon S3, reducing the need for S3 to make requests to AWS KMS to complete encryption operations. This reduces traffic from S3 to AWS KMS, allowing you to access AWS KMS-encrypted objects in Amazon S3 at a fraction of the previous cost.

Unique bucket-level keys are fetched at least once per requester to ensure that the requester's access to the key is captured in an AWS KMS CloudTrail event. Amazon S3 treats callers as different requesters when they use different roles or accounts, or the same role with different scoping policies. AWS KMS request savings reflect the number of requesters, request patterns, and relative age of the objects requested. For example, a fewer number of requesters, requesting multiple objects in a limited time window, and encrypted with the same bucket-level key, results in greater savings.

 **Note**

Using S3 Bucket Keys allows you to save on AWS KMS request costs by decreasing your requests to AWS KMS for Encrypt, GenerateDataKey, and Decrypt operations through the use of a bucket-level key. By design, subsequent requests that take advantage of this

bucket-level key do not result in AWS KMS API requests or validate access against the AWS KMS key policy.

When you configure an S3 Bucket Key, objects that are already in the bucket do not use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see [Configuring an S3 Bucket Key at the object level](#).

Amazon S3 will only share an S3 Bucket Key for objects encrypted by the same AWS KMS key. S3 Bucket Keys are compatible with KMS keys created by AWS KMS, [imported key material](#), and [key material backed by custom key stores](#).

Server-side encryption with AWS Key Management service using an S3 Bucket Key

Configuring S3 Bucket Keys

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects through the Amazon S3 console, AWS SDKs, AWS CLI, or REST API. With S3 Bucket Keys enabled on your

bucket, objects uploaded with a different specified SSE-KMS key will use their own S3 Bucket Keys. Regardless of your S3 Bucket Key setting, you can include the `x-amz-server-side-encryption-bucket-key-enabled` header with a true or false value in your request, to override the bucket setting.

Before you configure your bucket to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Configuring an S3 Bucket Key using the Amazon S3 console

When you create a new bucket, you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also configure an existing bucket to use an S3 Bucket Key for SSE-KMS on new objects by updating your bucket properties.

For more information, see [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#).

REST API, AWS CLI, and AWS SDK support for S3 Bucket Keys

You can use the REST API, AWS CLI, or AWS SDK to configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. You can also enable an S3 Bucket Key at the object level.

For more information, see the following:

- [Configuring an S3 Bucket Key at the object level](#)
- [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#)

The following API operations support S3 Bucket Keys for SSE-KMS:

- [PutBucketEncryption](#)
 - ServerSideEncryptionRule accepts the BucketKeyEnabled parameter for enabling and disabling an S3 Bucket Key.
- [GetBucketEncryption](#)
 - ServerSideEncryptionRule returns the settings for BucketKeyEnabled.
- [PutObject](#), [CopyObject](#), [CreateMultipartUpload](#), and [POST Object](#)
 - The `x-amz-server-side-encryption-bucket-key-enabled` request header enables or disables an S3 Bucket Key at the object level.
- [HeadObject](#), [GetObject](#), [UploadPartCopy](#), [UploadPart](#), and [CompleteMultipartUpload](#)

- The `x-amz-server-side-encryption-bucket-key-enabled` response header indicates if an S3 Bucket Key is enabled or disabled for an object.

Working with AWS CloudFormation

In AWS CloudFormation, the `AWS::S3::Bucket` resource includes an encryption property called `BucketKeyEnabled` that you can use to enable or disable an S3 Bucket Key.

For more information, see [Using AWS CloudFormation](#).

Changes to note before enabling an S3 Bucket Key

Before you enable an S3 Bucket Key, note the following related changes:

IAM or AWS KMS key policies

If your existing AWS Identity and Access Management (IAM) policies or AWS KMS key policies use your object Amazon Resource Name (ARN) as the encryption context to refine or limit access to your KMS key, these policies won't work with an S3 Bucket Key. S3 Bucket Keys use the bucket ARN as encryption context. Before you enable an S3 Bucket Key, update your IAM policies or AWS KMS key policies to use your bucket ARN as the encryption context.

For more information about the encryption context and S3 Bucket Keys, see [Encryption context](#).

CloudTrail events for AWS KMS

After you enable an S3 Bucket Key, your AWS KMS CloudTrail events log your bucket ARN instead of your object ARN. Additionally, you see fewer KMS CloudTrail events for SSE-KMS objects in your logs. Because key material is time-limited in Amazon S3, fewer requests are made to AWS KMS.

Using an S3 Bucket Key with replication

You can use S3 Bucket Keys with Same-Region Replication (SRR) and Cross-Region Replication (CRR).

When Amazon S3 replicates an encrypted object, it generally preserves the encryption settings of the replica object in the destination bucket. However, if the source object is not encrypted and your destination bucket uses default encryption or an S3 Bucket Key, Amazon S3 encrypts the object with the destination bucket's configuration.

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Example Example 1 – Source object uses S3 Bucket Keys; destination bucket uses default encryption

If your source object uses an S3 Bucket Key but your destination bucket uses default encryption with SSE-KMS, the replica object maintains its S3 Bucket Key encryption settings in the destination bucket. The destination bucket still uses default encryption with SSE-KMS.

Example Example 2 – Source object is not encrypted; destination bucket uses an S3 Bucket Key with SSE-KMS

If your source object is not encrypted and the destination bucket uses an S3 Bucket Key with SSE-KMS, the replica object is encrypted by using an S3 Bucket Key with SSE-KMS in the destination bucket. This results in the ETag of the source object being different from the ETag of the replica object. You must update applications that use the ETag to accommodate for this difference.

Working with S3 Bucket Keys

For more information about enabling and working with S3 Bucket Keys, see the following sections:

- [Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects](#)
- [Configuring an S3 Bucket Key at the object level](#)
- [Viewing the settings for an S3 Bucket Key](#)

Configuring your bucket to use an S3 Bucket Key with SSE-KMS for new objects

When you configure server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), you can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects. S3 Bucket Keys decrease the request traffic from Amazon S3 to AWS KMS and reduce the cost of SSE-KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

You can configure your bucket to use an S3 Bucket Key for SSE-KMS on new objects by using the Amazon S3 console, REST API, AWS SDKs, AWS Command Line Interface (AWS CLI), or AWS CloudFormation. If you want to enable or disable an S3 Bucket Key for existing objects, you can use a CopyObject operation. For more information, see [Configuring an S3 Bucket Key at the object level](#) and [Using Batch Operations to enable S3 Bucket Keys for SSE-KMS](#).

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket Amazon Resource Name (ARN) and not the object ARN, for example,

`arn:aws:s3:::bucket_ARN`. You need to update your IAM policies to use the bucket ARN for the encryption context. For more information, see [S3 Bucket Keys and replication](#).

The following examples illustrate how an S3 Bucket Key works with replication. For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Prerequisites

Before you configure your bucket to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Using the S3 console

In the S3 console, you can enable or disable an S3 Bucket Key for a new or existing bucket. Objects in the S3 console inherit their S3 Bucket Key setting from the bucket configuration. When you enable an S3 Bucket Key for your bucket, new objects that you upload to the bucket use an S3 Bucket Key for SSE-KMS.

Uploading, copying, or modifying objects in buckets that have an S3 Bucket Key enabled

If you upload, modify, or copy an object in a bucket that has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object might be updated to align with the bucket configuration.

If an object already has an S3 Bucket Key enabled, the S3 Bucket Key settings for that object don't change when you copy or modify the object. However, if you modify or copy an object that doesn't have an S3 Bucket Key enabled, and the destination bucket has an S3 Bucket Key configuration, the object inherits the destination bucket's S3 Bucket Key settings. For example, if your source object doesn't have an S3 Bucket Key enabled but the destination bucket has S3 Bucket Key enabled, an S3 Bucket Key is enabled for the object.

To enable an S3 Bucket Key when you create a new bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. Choose **Create bucket**.
4. Enter your bucket name, and choose your AWS Region.
5. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.

6. Under **AWS KMS key**, do one of the following to choose your KMS key:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list.

For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.

7. Under **Bucket Key**, choose **Enable**.

8. Choose **Create bucket**.

Amazon S3 creates your bucket with an S3 Bucket Key enabled. New objects that you upload to the bucket will use an S3 Bucket Key.

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

To enable an S3 Bucket Key for an existing bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose the **Properties** tab.
5. Under **Default encryption**, choose **Edit**.
6. Under **Default encryption**, for **Encryption key type**, choose **AWS Key Management Service key (SSE-KMS)**.
7. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list.

For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.

8. Under **Bucket Key**, choose **Enable**.

9. Choose **Save changes**.

Amazon S3 enables an S3 Bucket Key for new objects added to your bucket. Existing objects don't use the S3 Bucket Key. To configure an S3 Bucket Key for existing objects, you can use a `CopyObject` operation. For more information, see [Configuring an S3 Bucket Key at the object level](#).

To disable an S3 Bucket Key, follow the previous steps, and choose **Disable**.

Using the REST API

You can use [PutBucketEncryption](#) to enable or disable an S3 Bucket Key for your bucket. To configure an S3 Bucket Key with `PutBucketEncryption`, use the [ServerSideEncryptionRule](#) data type, which includes default encryption with SSE-KMS. You can also optionally use a customer managed key by specifying the KMS key ID for the customer managed key.

For more information and example syntax, see [PutBucketEncryption](#).

Using the AWS SDK for Java

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();
```

```
ServerSideEncryptionByDefault serverSideEncryptionByDefault = new
    ServerSideEncryptionByDefault()
        .withSSEAlgorithm(SSEAlgorithm.KMS);
ServerSideEncryptionRule rule = new ServerSideEncryptionRule()
    .withApplyServerSideEncryptionByDefault(serverSideEncryptionByDefault)
    .withBucketKeyEnabled(true);
ServerSideEncryptionConfiguration serverSideEncryptionConfiguration =
    new ServerSideEncryptionConfiguration().withRules(Collections.singleton(rule));

SetBucketEncryptionRequest setBucketEncryptionRequest = new
    SetBucketEncryptionRequest()
        .withServerSideEncryptionConfiguration(serverSideEncryptionConfiguration)
        .withBucketName(bucketName);

s3client.setBucketEncryption(setBucketEncryptionRequest);
```

Using the AWS CLI

The following example enables default bucket encryption with SSE-KMS and an S3 Bucket Key by using the AWS CLI. Replace the *user input placeholders* with your own information.

```
aws s3api put-bucket-encryption --bucket amzn-s3-demo-bucket --server-side-encryption-
configuration '{
    "Rules": [
        {
            "ApplyServerSideEncryptionByDefault": {
                "SSEAlgorithm": "aws:kms",
                "KMSMasterKeyID": "KMS-Key-ARN"
            },
            "BucketKeyEnabled": true
        }
    ]
}'
```

Using AWS CloudFormation

For more information about configuring an S3 Bucket Key with AWS CloudFormation, see [AWS::S3::Bucket ServerSideEncryptionRule](#) in the *AWS CloudFormation User Guide*.

Configuring an S3 Bucket Key at the object level

When you perform a PUT or COPY operation using the REST API, AWS SDKs, or AWS CLI, you can enable or disable an S3 Bucket Key at the object level by adding the `x-amz-server-side-encryption-bucket-key-enabled` request header with a true or false value. S3 Bucket Keys reduce the cost of server-side encryption using AWS Key Management Service (AWS KMS) (SSE-KMS) by decreasing request traffic from Amazon S3 to AWS KMS. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

When you configure an S3 Bucket Key for an object using a PUT or COPY operation, Amazon S3 only updates the settings for that object. The S3 Bucket Key settings for the destination bucket do not change. If you submit a PUT or COPY request for a KMS-encrypted object into a bucket with S3 Bucket Keys enabled, your object level operation will automatically use S3 Bucket Keys unless you disable the keys in the request header. If you don't specify an S3 Bucket Key for your object, Amazon S3 applies the S3 Bucket Key settings for the destination bucket to the object.

Prerequisite:

Before you configure your object to use an S3 Bucket Key, review [Changes to note before enabling an S3 Bucket Key](#).

Topics

- [Amazon S3 Batch Operations](#)
- [Using the REST API](#)
- [Using the AWS SDK for Java \(PutObject\)](#)
- [Using the AWS CLI \(PutObject\)](#)

Amazon S3 Batch Operations

To encrypt your existing Amazon S3 objects, you can use Amazon S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on, and Batch Operations calls the respective API to perform the specified operation.

You can use the [S3 Batch Operations Copy operation](#) to copy existing unencrypted objects and write them back to the same bucket as encrypted objects. A single Batch Operations job can perform the specified operation on billions of objects. For more information, see [Performing object operations in bulk with Batch Operations](#) and [Encrypting objects with Amazon S3 Batch Operations](#).

Using the REST API

When you use SSE-KMS, you can enable an S3 Bucket Key for an object by using the following API operations:

- [PutObject](#) – When you upload an object, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key at the object level.
- [CopyObject](#) – When you copy an object and configure SSE-KMS, you can specify the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.
- [POST Object](#) – When you use a POST operation to upload an object and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` form field to enable or disable an S3 Bucket Key for your object.
- [CreateMultipartUpload](#) – When you upload large objects by using the `CreateMultipartUpload` API operation and configure SSE-KMS, you can use the `x-amz-server-side-encryption-bucket-key-enabled` request header to enable or disable an S3 Bucket Key for your object.

To enable an S3 Bucket Key at the object level, include the `x-amz-server-side-encryption-bucket-key-enabled` request header. For more information about SSE-KMS and the REST API, see [Using the REST API](#).

Using the AWS SDK for Java ([PutObject](#))

You can use the following example to configure an S3 Bucket Key at the object level using the AWS SDK for Java.

Java

```
AmazonS3 s3client = AmazonS3ClientBuilder.standard()
    .withRegion(Regions.DEFAULT_REGION)
    .build();

String bucketName = "amzn-s3-demo-bucket1";
String keyName = "key name for object";
String contents = "file contents";
```

```
PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName, keyName,
    contents)
    .withBucketKeyEnabled(true);

s3client.putObject(putObjectRequest);
```

Using the AWS CLI (PutObject)

You can use the following AWS CLI example to configure an S3 Bucket Key at the object level as part of a PutObject request.

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key object key name --server-side-encryption aws:kms --bucket-key-enabled --body filepath
```

Viewing the settings for an S3 Bucket Key

You can view the settings for an S3 Bucket Key at the bucket or object level by using the Amazon S3 console, REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs.

S3 Bucket Keys decrease request traffic from Amazon S3 to AWS KMS and reduce the cost of server-side encryption using AWS Key Management Service (SSE-KMS). For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

To view the S3 Bucket Key settings for a bucket or an object that has inherited S3 Bucket Key settings from the bucket configuration, you need permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see [GetBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

Using the S3 console

In the S3 console, you can view the S3 Bucket Key settings for your bucket or object. S3 Bucket Key settings are inherited from the bucket configuration unless the source objects already has an S3 Bucket Key configured.

Objects and folders in the same bucket can have different S3 Bucket Key settings. For example, if you upload an object using the REST API and enable an S3 Bucket Key for the object, the object retains its S3 Bucket Key setting in the destination bucket, even if S3 Bucket Key is disabled in the destination bucket. As another example, if you enable an S3 Bucket Key for an existing bucket, objects that are already in the bucket do not use an S3 Bucket Key. However, new objects have an S3 Bucket Key enabled.

To view the S3 Bucket Key setting for your bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
4. Choose **Properties**.
5. In the **Default encryption** section, under **Bucket Key**, you see the S3 Bucket Key setting for your bucket.

If you can't see the S3 Bucket Key setting, you might not have permission to perform the `s3:GetEncryptionConfiguration` action. For more information, see [GetBucketEncryption](#) in the *Amazon Simple Storage Service API Reference*.

To view the S3 Bucket Key setting for your object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the bucket that you want to enable an S3 Bucket Key for.
3. In the **Objects** list, choose your object name.
4. On the **Details** tab, under **Server-side encryption settings**, choose **Edit**.

Under **Bucket Key**, you see the S3 Bucket Key setting for your object. You cannot edit this setting.

Using the AWS CLI

To return bucket-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api get-bucket-encryption --bucket amzn-s3-demo-bucket1
```

For more information, see [get-bucket-encryption](#) in the *AWS CLI Command Reference*.

To return object-level S3 Bucket Key settings

To use this example, replace each *user input placeholder* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-bucket1 --key my_images.tar.bz2
```

For more information, see [head-object](#) in the *AWS CLI Command Reference*.

Using the REST API

To return bucket-level S3 Bucket Key settings

To return encryption information for a bucket, including the settings for an S3 Bucket Key, use the `GetBucketEncryption` operation. S3 Bucket Key settings are returned in the response body in the `ServerSideEncryptionConfiguration` element with the `BucketKeyEnabled` setting. For more information, see [GetBucketEncryption](#) in the *Amazon S3 API Reference*.

To return object-level settings for an S3 Bucket Key

To return the S3 Bucket Key status for an object, use the `HeadObject` operation. `HeadObject` returns the `x-amz-server-side-encryption-bucket-key-enabled` response header to show whether an S3 Bucket Key is enabled or disabled for the object. For more information, see [HeadObject](#) in the *Amazon S3 API Reference*.

The following API operations also return the `x-amz-server-side-encryption-bucket-key-enabled` response header if an S3 Bucket Key is configured for an object:

- [PutObject](#)
- [PostObject](#)
- [CopyObject](#)
- [CreateMultipartUpload](#)
- [UploadPartCopy](#)
- [UploadPart](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)

Using dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

Using dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. DSSE-KMS

helps you more easily fulfill compliance standards that require you to apply multilayer encryption to your data and have full control of your encryption keys.

When you use DSSE-KMS with an Amazon S3 bucket, the AWS KMS keys must be in the same Region as the bucket. Also, when DSSE-KMS is requested for the object, the S3 checksum that's part of the object's metadata is stored in encrypted form. For more information about checksums, see [Checking object integrity in Amazon S3](#).

There are additional charges for using DSSE-KMS and AWS KMS keys. For more information about DSSE-KMS pricing, see [AWS KMS key concepts](#) in the *AWS Key Management Service Developer Guide* and [AWS KMS pricing](#).

 **Note**

S3 Bucket Keys aren't supported for DSSE-KMS.

Requiring dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

To require dual-layer server-side encryption of all objects in a particular Amazon S3 bucket, you can use a bucket policy. For example, the following bucket policy denies the upload object (`s3:PutObject`) permission to everyone if the request does not include an `x-amz-server-side-encryption` header that requests server-side encryption with DSSE-KMS.

```
{  
    "Version": "2012-10-17",  
    "Id": "PutObjectPolicy",  
    "Statement": [  
        {  
            "Sid": "DenyUnEncryptedObjectUploads",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",  
            "Condition": {  
                "StringNotEquals": {  
                    "s3:x-amz-server-side-encryption": "aws:kms:dsse"  
                }  
            }  
        }  
    ]  
}
```

Topics

- [Specifying dual-layer server-side encryption with AWS KMS keys \(DSSE-KMS\)](#)

Specifying dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)

You can apply encryption when you are either uploading a new object or copying an existing object.

You can specify DSSE-KMS by using the Amazon S3 console, Amazon S3 REST API, and the AWS Command Line Interface (AWS CLI). For more information, see the following topics.

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Note

If you want to use a KMS key that is owned by a different account, you must have permission to use the key. For more information about cross-account permissions for KMS keys, see [Creating KMS keys that other accounts can use](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

This section describes how to set or change the type of encryption of an object to use dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) by using the Amazon S3 console.

Note

- You can change an object's encryption if your object is less than 5 GB. If your object is greater than 5 GB, you must use the [AWS CLI](#) or [AWS SDKs](#) to change an object's encryption.

- For a list of additional permissions required to change an object's encryption, see [the section called "Required permissions for S3 API operations"](#). For example policies that grant this permission, see [the section called "Identity-based policy examples"](#).
- If you change an object's encryption, a new object is created to replace the old one. If S3 Versioning is enabled, a new version of the object is created, and the existing object becomes an older version. The role that changes the property also becomes the owner of the new object (or object version).

To add or change encryption for an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the **General purpose buckets** tab. Navigate to the Amazon S3 bucket or folder that contains the objects you want to change.
3. Select the check box for the objects you want to change.
4. On the **Actions** menu, choose **Edit server-side encryption** from the list of options that appears.
5. Scroll to the **Server-side encryption** section.
6. Under **Encryption settings**, choose **Use bucket settings for default encryption** or **Override bucket settings for default encryption**.
7. If you chose **Override bucket settings for default encryption**, configure the following encryption settings.
 - a. Under **Encryption type**, choose **Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)**.
 - b. Under **AWS KMS key**, do one of the following to choose your KMS key:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and then choose your **KMS key** from the list of available keys.Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the [AWS Key Management Service Developer Guide](#).
 - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and then enter your KMS key ARN in the field that appears.

- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

You can use only KMS keys that are available in the same AWS Region as the bucket. The Amazon S3 console lists only the first 100 KMS keys in the same Region as the bucket. To use a KMS key that is not listed, you must enter your KMS key ARN. If you want to use a KMS key that is owned by a different account, you must first have permission to use the key, and then you must enter the KMS key ARN.

Amazon S3 supports only symmetric encryption KMS keys, and not asymmetric KMS keys. For more information, see [Identifying asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*.

8. For **Bucket Key**, choose **Disable**. S3 Bucket Keys aren't supported for DSSE-KMS.
9. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
10. Choose **Save changes**.

 **Note**

This action applies encryption to all specified objects. When you're encrypting folders, wait for the save operation to finish before adding new objects to the folder.

Using the REST API

When you create an object—that is, when you upload a new object or copy an existing object—you can specify the use of dual-layer server-side encryption with AWS KMS keys (DSSE-KMS) to encrypt

your data. To do this, add the `x-amz-server-side-encryption` header to the request. Set the value of the header to the encryption algorithm `aws:kms:dsse`. Amazon S3 confirms that your object is stored with DSSE-KMS encryption by returning the response header `x-amz-server-side-encryption`.

If you specify the `x-amz-server-side-encryption` header with a value of `aws:kms:dsse`, you can also use the following request headers:

- `x-amz-server-side-encryption-aws-kms-key-id`: *SSEKMSKeyId*
- `x-amz-server-side-encryption-context`: *SSEKMSEncryptionContext*

Topics

- [Amazon S3 REST API operations that support DSSE-KMS](#)
- [Encryption context \(x-amz-server-side-encryption-context\)](#)
- [AWS KMS key ID \(x-amz-server-side-encryption-aws-kms-key-id\)](#)

Amazon S3 REST API operations that support DSSE-KMS

The following REST API operations accept the `x-amz-server-side-encryption`, `x-amz-server-side-encryption-aws-kms-key-id`, and `x-amz-server-side-encryption-context` request headers.

- [**PutObject**](#) – When you upload data by using the PUT API operation, you can specify these request headers.
- [**CopyObject**](#) – When you copy an object, you have both a source object and a target object. When you pass DSSE-KMS headers with the CopyObject operation, they are applied only to the target object. When you're copying an existing object, regardless of whether the source object is encrypted or not, the destination object is not encrypted unless you explicitly request server-side encryption.
- [**POST Object**](#) – When you use a POST operation to upload an object, instead of the request headers, you provide the same information in the form fields.
- [**CreateMultipartUpload**](#) – When you upload large objects by using a multipart upload, you can specify these headers in the CreateMultipartUpload request.

The response headers of the following REST API operations return the `x-amz-server-side-encryption` header when an object is stored with server-side encryption.

- [PutObject](#)
- [CopyObject](#)
- [POST Object](#)
- [CreateMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [CompleteMultipartUpload](#)
- [GetObject](#)
- [HeadObject](#)

Important

- All GET and PUT requests for an object that's protected by AWS KMS fail if you don't make them by using Secure Sockets Layer (SSL), Transport Layer Security (TLS), or Signature Version 4.
- If your object uses DSSE-KMS, don't send encryption request headers for GET requests and HEAD requests, or you'll get an HTTP 400 (Bad Request) error.

Encryption context (`x-amz-server-side-encryption-context`)

If you specify `x-amz-server-side-encryption:aws:kms:dsse`, the Amazon S3 API supports an encryption context with the `x-amz-server-side-encryption-context` header. An encryption context is a set of key-value pairs that contain additional contextual information about the data.

Amazon S3 automatically uses the object's Amazon Resource Name (ARN) as the encryption context pair; for example, `arn:aws:s3:::object_ARN`.

You can optionally provide an additional encryption context pair by using the `x-amz-server-side-encryption-context` header. However, because the encryption context is not encrypted, make sure it does not include sensitive information. Amazon S3 stores this additional key pair alongside the default encryption context.

For information about the encryption context in Amazon S3, see [Encryption context](#). For general information about the encryption context, see [AWS Key Management Service Concepts - Encryption context](#) in the *AWS Key Management Service Developer Guide*.

AWS KMS key ID (`x-amz-server-side-encryption-aws-kms-key-id`)

You can use the `x-amz-server-side-encryption-aws-kms-key-id` header to specify the ID of the customer managed key that's used to protect the data. If you specify the `x-amz-server-side-encryption:aws:kms:dsse` header but don't provide the `x-amz-server-side-encryption-aws-kms-key-id` header, Amazon S3 uses the AWS managed key (aws/s3) to protect the data. If you want to use a customer managed key, you must provide the `x-amz-server-side-encryption-aws-kms-key-id` header of the customer managed key.

Important

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys. For more information about these keys, see [Symmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

Using the AWS CLI

When you upload a new object or copy an existing object, you can specify the use of DSSE-KMS to encrypt your data. To do this, add the `--server-side-encryption aws:kms:dsse` parameter to the request. Use the `--ssekms-key-id example-key-id` parameter to add your [customer managed AWS KMS key](#) that you created. If you specify `--server-side-encryption aws:kms:dsse`, but do not provide an AWS KMS key ID, then Amazon S3 will use the AWS managed key (aws/s3).

```
aws s3api put-object --bucket amzn-s3-demo-bucket --key example-object-key --server-side-encryption aws:kms:dsse --ssekms-key-id example-key-id --body filepath
```

You can encrypt an unencrypted object to use DSSE-KMS by copying the object back in place.

```
aws s3api copy-object --bucket amzn-s3-demo-bucket --key example-object-key --body filepath --bucket amzn-s3-demo-bucket --key example-object-key --sse aws:kms:dsse --sse-kms-key-id example-key-id --body filepath
```

Using server-side encryption with customer-provided keys (SSE-C)

Server-side encryption is about protecting data at rest. Server-side encryption encrypts only the object data, not the object metadata. By using server-side encryption with customer-provided keys (SSE-C), you can store your data encrypted with your own encryption keys. With the encryption key that you provide as part of your request, Amazon S3 manages data encryption as it writes to disks and data decryption when you access your objects. Therefore, you don't need to maintain any code to perform data encryption and decryption. The only thing that you need to do is manage the encryption keys that you provide.

When you upload an object, Amazon S3 uses the encryption key that you provide to apply AES-256 encryption to your data. Amazon S3 then removes the encryption key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. Amazon S3 first verifies that the encryption key that you provided matches, and then it decrypts the object before returning the object data to you.

There are no additional charges for using SSE-C. However, requests to configure and use SSE-C incur standard Amazon S3 request charges. For information about pricing, see [Amazon S3 pricing](#).

Note

Amazon S3 does not store the encryption key that you provide. Instead, it stores a randomly salted Hash-based Message Authentication Code (HMAC) value of the encryption key to validate future requests. The salted HMAC value cannot be used to derive the value of the encryption key or to decrypt the contents of the encrypted object. That means if you lose the encryption key, you lose the object.

S3 Replication supports objects that are encrypted with SSE-C. For more information about replicating encrypted objects, see [the section called “Replicating encrypted objects”](#).

For more information about SSE-C, see the following topics.

Topics

- [SSE-C overview](#)
- [Requiring and restricting SSE-C](#)
- [Presigned URLs and SSE-C](#)
- [Specifying server-side encryption with customer-provided keys \(SSE-C\)](#)

SSE-C overview

This section provides an overview of SSE-C. When using SSE-C, keep the following considerations in mind.

- You must use HTTPS.

Important

Amazon S3 rejects any requests made over HTTP when using SSE-C. For security considerations, we recommend that you consider any key that you erroneously send over HTTP to be compromised. Discard the key and rotate as appropriate.

- The entity tag (ETag) in the response is not the MD5 hash of the object data.
- You manage a mapping of which encryption key was used to encrypt which object. Amazon S3 does not store encryption keys. You are responsible for tracking which encryption key you provided for which object.
 - If your bucket is versioning-enabled, each object version that you upload by using this feature can have its own encryption key. You are responsible for tracking which encryption key was used for which object version.
 - Because you manage encryption keys on the client side, you manage any additional safeguards, such as key rotation, on the client side.

Warning

If you lose the encryption key, any GET request for an object without its encryption key fails, and you lose the object.

Requiring and restricting SSE-C

To require SSE-C for all objects in a particular Amazon S3 bucket, you can use a bucket policy.

For example, the following bucket policy denies upload object (`s3:PutObject`) permissions for all requests that don't include the `x-amz-server-side-encryption-customer-algorithm` header requesting SSE-C.

{

```
"Version": "2012-10-17",
"Id": "PutObjectPolicy",
"Statement": [
    {
        "Sid": "RequireSSECObjectUploads",
        "Effect": "Deny",
        "Principal": "*",
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "Condition": {
            "Null": {
                "s3:x-amz-server-side-encryption-customer-algorithm": "true"
            }
        }
    }
]
```

You can also use a policy to restrict server-side encryption of all objects in a particular Amazon S3 bucket. For example, the following bucket policy denies the upload object (s3:PutObject) permission to everyone if the request includes the x-amz-server-side-encryption-customer-algorithm header requesting SSE-C.

```
{
    "Version": "2012-10-17",
    "Id": "PutObjectPolicy",
    "Statement": [
        {
            "Sid": "RestrictSSECObjectUploads",
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "Null": {
                    "s3:x-amz-server-side-encryption-customer-algorithm": "false"
                }
            }
        }
    ]
}
```

⚠ Important

If you use a bucket policy to require SSE-C on `s3:PutObject`, you must include the `x-amz-server-side-encryption-customer-algorithm` header in all multipart upload requests (`CreateMultipartUpload`, `UploadPart`, and `CompleteMultipartUpload`).

Presigned URLs and SSE-C

You can generate a presigned URL that can be used for operations such as uploading a new object, retrieving an existing object, or retrieving object metadata. Presigned URLs support SSE-C as follows:

- When creating a presigned URL, you must specify the algorithm by using the `x-amz-server-side-encryption-customer-algorithm` header in the signature calculation.
- When using the presigned URL to upload a new object, retrieve an existing object, or retrieve only object metadata, you must provide all the encryption headers in your client application's request.

 ⓘ Note

For non-SSE-C objects, you can generate a presigned URL and directly paste that URL into a browser to access the data.

However, you cannot do this for SSE-C objects, because in addition to the presigned URL, you also must include HTTP headers that are specific to SSE-C objects. Therefore, you can use presigned URLs for SSE-C objects only programmatically.

For more information about presigned URLs, see [the section called “Using presigned URLs to download and upload objects”](#).

Specifying server-side encryption with customer-provided keys (SSE-C)

At the time of object creation with the REST API, you can specify server-side encryption with customer-provided keys (SSE-C). When you use SSE-C, you must provide encryption key information using the following request headers.

Name	Description
x-amz-server-side-encryption-customer-algorithm	Use this header to specify the encryption algorithm. The header value must be AES256.
x-amz-server-side-encryption-customer-key	Use this header to provide the 256-bit, base64-encoded encryption key for Amazon S3 to use to encrypt or decrypt your data.
x-amz-server-side-encryption-customer-key-MD5	Use this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321 . Amazon S3 uses this header for a message integrity check to ensure that the encryption key was transmitted without error.

You can use AWS SDK wrapper libraries to add these headers to your request. If you need to, you can make the Amazon S3 REST API calls directly in your application.

Note

You cannot use the Amazon S3 console to upload an object and request SSE-C. You also cannot use the console to update (for example, change the storage class or add metadata) an existing object stored using SSE-C.

Using the REST API

Amazon S3 rest APIs that support SSE-C

The following Amazon S3 APIs support server-side encryption with customer-provided encryption keys (SSE-C).

- **GET operation** – When retrieving objects using the GET API (see [GET Object](#)), you can specify the request headers.
- **HEAD operation** – To retrieve object metadata using the HEAD API (see [HEAD Object](#)), you can specify these request headers.

- **PUT operation** – When uploading data using the PUT Object API (see [PUT Object](#)), you can specify these request headers.
- **Multipart Upload** – When uploading large objects using the multipart upload API, you can specify these headers. You specify these headers in the initiate request (see [Initiate Multipart Upload](#)) and each subsequent part upload request (see [Upload Part](#) or [Upload Part - Copy](#)). For each part upload request, the encryption information must be the same as what you provided in the initiate multipart upload request.
- **POST operation** – When using a POST operation to upload an object (see [POST Object](#)), instead of the request headers, you provide the same information in the form fields.
- **Copy operation** – When you copy an object (see [PUT Object - Copy](#)), you have both a source object and a target object:
 - If you want the target object encrypted using server-side encryption with AWS managed keys, you must provide the `x-amz-server-side-encryption` request header.
 - If you want the target object encrypted using SSE-C, you must provide encryption information using the three headers described in the preceding table.
 - If the source object is encrypted using SSE-C, you must provide encryption key information using the following headers so that Amazon S3 can decrypt the object for copying.

Name	Description
<code>x-amz-copy-source-server-side-encryption-algorithm</code>	Include this header to specify the algorithm Amazon S3 should use to decrypt the source object. This value must be AES256.
<code>x-amz-copy-source-server-side-encryption-customer-key</code>	Include this header to provide the base64-encoded encryption key for Amazon S3 to use to decrypt the source object. This encryption key must be the one that you provided Amazon S3 when you created the source object. Otherwise, Amazon S3 cannot decrypt the object.
<code>x-amz-copy-source-server-side-encryption</code>	Include this header to provide the base64-encoded 128-bit MD5 digest of the encryption key according to RFC 1321 .

Name	Description
-customer-key-	
MD5	

Using the AWS SDKs to specify SSE-C for PUT, GET, Head, and Copy operations

The following examples show how to request server-side encryption with customer-provided keys (SSE-C) for objects. The examples perform the following operations. Each operation shows how to specify SSE-C-related headers in the request:

- **Put object** – Uploads an object and requests server-side encryption using a customer-provided encryption key.
- **Get object** – Downloads the object uploaded in the previous step. In the request, you provide the same encryption information you provided when you uploaded the object. Amazon S3 needs this information to decrypt the object so that it can return it to you.
- **Get object metadata** – Retrieves the object's metadata. You provide the same encryption information used when the object was created.
- **Copy object** – Makes a copy of the previously-uploaded object. Because the source object is stored using SSE-C, you must provide its encryption information in your copy request. By default, Amazon S3 encrypts the copy of the object only if you explicitly request it. This example directs Amazon S3 to store an encrypted copy of the object.

Java

Note

This example shows how to upload an object in a single operation. When using the Multipart Upload API to upload large objects, you provide encryption information in the same way shown in this example. For examples of multipart uploads that use the AWS SDK for Java, see [Uploading an object using multipart upload](#).

To add the required encryption information, you include an `SSECUSTOMERKEY` in your request. For more information about the `SSECUSTOMERKEY` class, see the REST API section.

For information about SSE-C, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#). For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

Example

```

    };  
    await client.CopyObjectAsync(copyRequest);  
}
```

```
}
```

Using the AWS SDKs to specify SSE-C for multipart uploads

The example in the preceding section shows how to request server-side encryption with customer-provided key (SSE-C) in the PUT, GET, Head, and Copy operations. This section describes other Amazon S3 APIs that support SSE-C.

Java

To upload large objects, you can use multipart upload API (see [Uploading and copying objects using multipart upload in Amazon S3](#)). You can use either high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using the high-level TransferManager API, you provide the encryption-specific headers in the PutObjectRequest (see [Uploading an object using multipart upload](#)).
- When using the low-level API, you provide encryption-related information in the InitiateMultipartUploadRequest, followed by identical encryption information in each UploadPartRequest. You do not need to provide any encryption-specific headers in your CompleteMultipartUploadRequest. For examples, see [Using the AWS SDKs \(low-level API\)](#).

The following example uses TransferManager to create objects and shows how to provide SSE-C related information. The example does the following:

- Creates an object using the TransferManager.upload() method. In the PutObjectRequest instance, you provide encryption key information to request. Amazon S3 encrypts the object using the customer-provided key.
- Makes a copy of the object by calling the TransferManager.copy() method. The example directs Amazon S3 to encrypt the object copy using a new SSECustomerKey. Because the source object is encrypted using SSE-C, the CopyObjectRequest also provides the encryption key of the source object so that Amazon S3 can decrypt the object before copying it.

Example

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.CopyObjectRequest;
import com.amazonaws.services.s3.model.PutObjectRequest;
import com.amazonaws.services.s3.model.SSECustomerKey;
import com.amazonaws.services.s3.transfer.Copy;
import com.amazonaws.services.s3.transfer.TransferManager;
import com.amazonaws.services.s3.transfer.TransferManagerBuilder;
import com.amazonaws.services.s3.transfer.Upload;

import javax.crypto.KeyGenerator;
import java.io.File;
import java.security.SecureRandom;

public class ServerSideEncryptionCopyObjectUsingHLwithSSEC {

    public static void main(String[] args) throws Exception {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String bucketName = "*** Bucket name ***";
        String fileToUpload = "*** File path ***";
        String keyName = "*** New object key name ***";
        String targetKeyName = "*** Key name for object copy ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withRegion(clientRegion)
                .withCredentials(new ProfileCredentialsProvider())
                .build();
            TransferManager tm = TransferManagerBuilder.standard()
                .withS3Client(s3Client)
                .build();

            // Create an object from a file.
            PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName,
keyName, new File(fileToUpload));

            // Create an encryption key.
```

```
        KeyGenerator keyGenerator = KeyGenerator.getInstance("AES");
        keyGenerator.init(256, new SecureRandom());
        SSECustomerKey sseCustomerEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());

        // Upload the object. TransferManager uploads asynchronously, so this
call
        // returns immediately.
        putObjectRequest.setSSECustomerKey(sseCustomerEncryptionKey);
        Upload upload = tm.upload(putObjectRequest);

        // Optionally, wait for the upload to finish before continuing.
        upload.waitForCompletion();
        System.out.println("Object created.");

        // Copy the object and store the copy using SSE-C with a new key.
        CopyObjectRequest copyObjectRequest = new CopyObjectRequest(bucketName,
keyName, bucketName, targetKeyName);
        SSECustomerKey sseTargetObjectEncryptionKey = new
SSECustomerKey(keyGenerator.generateKey());
        copyObjectRequest.setSourceSSECustomerKey(sseCustomerEncryptionKey);

copyObjectRequest.setDestinationSSECustomerKey(sseTargetObjectEncryptionKey);

        // Copy the object. TransferManager copies asynchronously, so this call
returns
        // immediately.
        Copy copy = tm.copy(copyObjectRequest);

        // Optionally, wait for the upload to finish before continuing.
        copy.waitForCompletion();
        System.out.println("Copy complete.");
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

.NET

To upload large objects, you can use multipart upload API (see [Uploading and copying objects using multipart upload in Amazon S3](#)). AWS SDK for .NET provides both high-level or low-level APIs to upload large objects. These APIs support encryption-related headers in the request.

- When using high-level Transfer-Utility API, you provide the encryption-specific headers in the TransferUtilityUploadRequest as shown. For code examples, see [Uploading an object using multipart upload](#).

```
TransferUtilityUploadRequest request = new TransferUtilityUploadRequest()
{
    FilePath = filePath,
    BucketName = existingBucketName,
    Key = keyName,
    // Provide encryption information.
    ServerSideEncryptionCustomerMethod =
    ServerSideEncryptionCustomerMethod.AES256,
    ServerSideEncryptionCustomerProvidedKey = base64Key,
};
```

- When using the low-level API, you provide encryption-related information in the initiate multipart upload request, followed by identical encryption information in the subsequent upload part requests. You do not need to provide any encryption-specific headers in your complete multipart upload request. For examples, see [Using the AWS SDKs \(low-level API\)](#).

The following is a low-level multipart upload example that makes a copy of an existing large object. In the example, the object to be copied is stored in Amazon S3 using SSE-C, and you want to save the target object also using SSE-C. In the example, you do the following:

- Initiate a multipart upload request by providing an encryption key and related information.
- Provide source and target object encryption keys and related information in the CopyPartRequest.
- Obtain the size of the source object to be copied by retrieving the object metadata.
- Upload the objects in 5 MB parts.

Example

```
using Amazon;
```

```
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.IO;
using System.Security.Cryptography;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class SSECLowLevelMPUcopyObjectTest
    {
        private const string existingBucketName = "*** bucket name ***";
        private const string sourceKeyName      = "*** source object key name
***";
        private const string targetKeyName      = "*** key name for the target
object ***";
        private const string filePath           = @ "*** file path ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;
        static void Main()
        {
            s3Client = new AmazonS3Client(bucketRegion);
            CopyObjClientEncryptionKeyAsync().Wait();
        }

        private static async Task CopyObjClientEncryptionKeyAsync()
        {
            Aes aesEncryption = Aes.Create();
            aesEncryption.KeySize = 256;
            aesEncryption.GenerateKey();
            string base64Key = Convert.ToBase64String(aesEncryption.Key);

            await CreateSampleObjUsingClientEncryptionKeyAsync(base64Key,
s3Client);

            await CopyObjectAsync(s3Client, base64Key);
        }
        private static async Task CopyObjectAsync(IAmazonS3 s3Client, string
base64Key)
        {
            List<CopyPartResponse> uploadResponses = new List<CopyPartResponse>();
```

```
// 1. Initialize.
InitiateMultipartUploadRequest initiateRequest = new
InitiateMultipartUploadRequest

    };
    await s3Client.AbortMultipartUploadAsync(abortMPURequest);
}
}
}
```

Protecting data by using client-side encryption

Client-side encryption is the act of encrypting your data locally to help ensure its security in transit and at rest. To encrypt your objects before you send them to Amazon S3, use the Amazon S3 Encryption Client. When your objects are encrypted in this manner, your objects aren't exposed to any third party, including AWS. Amazon S3 receives your objects already encrypted; Amazon S3 does not play a role in encrypting or decrypting your objects. You can use both the Amazon S3 Encryption Client and [server-side encryption](#) to encrypt your data. When you send encrypted objects to Amazon S3, Amazon S3 doesn't recognize the objects as being encrypted, it only detects typical objects.

The Amazon S3 Encryption Client works as an intermediary between you and Amazon S3. After you instantiate the Amazon S3 Encryption Client, your objects are automatically encrypted and decrypted as part of your Amazon S3 PutObject and GetObject requests. Your objects are all encrypted with a unique data key. The Amazon S3 Encryption Client does not use or interact with bucket keys, even if you specify a KMS key as your wrapping key.

The *Amazon S3 Encryption Client Developer Guide* focuses on versions 3.0 and later of the Amazon S3 Encryption Client. For more information, see [What is the Amazon S3 Encryption Client?](#) in the *Amazon S3 Encryption Client Developer Guide*.

For more information about previous versions of the Amazon S3 Encryption client, see the AWS SDK Developer Guide for your programming language.

Internet traffic privacy

This topic describes how Amazon S3 secures connections from the service to other locations.

Traffic between service and on-premises clients and applications

The following connections can be combined with AWS PrivateLink to provide connectivity between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the [AWS Security Token Service \(STS\)](#) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same Region

A virtual private cloud (VPC) endpoint for Amazon S3 is a logical entity within a VPC that allows connectivity only to Amazon S3. The VPC routes requests to Amazon S3 and routes responses back to the VPC. For more information, see [VPC Endpoints](#) in the *VPC User Guide*. For example bucket policies that you can use to control S3 bucket access from VPC endpoints, see [Controlling access from VPC endpoints with bucket policies](#).

AWS PrivateLink for Amazon S3

With AWS PrivateLink for Amazon S3, you can provision *interface VPC endpoints* (interface endpoints) in your virtual private cloud (VPC). These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over VPC peering.

Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your VPC. Requests to Amazon S3 over interface endpoints stay on the Amazon network. You can also access interface endpoints in your VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your VPC with your on-premises network, see the [AWS Direct Connect User Guide](#) and the [AWS Site-to-Site VPN User Guide](#).

For general information about interface endpoints, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the *AWS PrivateLink Guide*.

Topics

- [Types of VPC endpoints for Amazon S3](#)
- [Restrictions and limitations of AWS PrivateLink for Amazon S3](#)
- [Creating a VPC endpoint](#)

- [Updating an on-premises DNS configuration](#)
- [Creating a VPC endpoint policy for Amazon S3](#)

Types of VPC endpoints for Amazon S3

You can use two types of VPC endpoints to access Amazon S3: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access Amazon S3 from your VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to Amazon S3 from within your VPC, on premises, or from a VPC in another AWS Region by using VPC peering

or AWS Transit Gateway. For more information, see [What is VPC peering?](#) and [Transit Gateway vs VPC peering](#).

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the VPC, you can use both types of endpoints in the same VPC.

Gateway endpoints for Amazon S3	Interface endpoints for Amazon S3
In both cases, your network traffic remains on the AWS network.	
Use Amazon S3 public IP addresses	Use private IP addresses from your VPC to access Amazon S3
Use the same Amazon S3 DNS names	Require endpoint-specific Amazon S3 DNS names
Do not allow access from on premises	Allow access from on premises
Do not allow access from another AWS Region	Allow access from a VPC in another AWS Region by using VPC peering or AWS Transit Gateway
Not billed	Billed

For more information about gateway endpoints, see [Gateway VPC endpoints](#) in the *AWS PrivateLink Guide*.

Restrictions and limitations of AWS PrivateLink for Amazon S3

VPC limitations apply to AWS PrivateLink for Amazon S3. For more information, see [Interface endpoint considerations](#) and [AWS PrivateLink quotas](#) in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

AWS PrivateLink for Amazon S3 does not support the following:

- [Federal Information Processing Standard \(FIPS\) endpoints](#)
- [Website endpoints](#)
- [Legacy global endpoints](#)
- [S3 dash Region endpoints](#)

- [Dual-stack endpoints](#)
- Using [CopyObject](#) or [UploadPartCopy](#) between buckets in different AWS Regions
- Transport Layer Security (TLS) 1.1

Creating a VPC endpoint

To create a VPC interface endpoint, see [Create a VPC endpoint](#) in the *AWS PrivateLink Guide*.

Accessing Amazon S3 interface endpoints

When you create an interface endpoint, Amazon S3 generates two types of endpoint-specific, S3 DNS names: *Regional* and *zonal*.

- A *Regional* DNS name includes a unique VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for VPC endpoint ID `vpce-1a2b3c4d`, the DNS name generated might be similar to `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, `vpce-1a2b3c4d-5e6f-us-east-1a.s3.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Endpoint-specific S3 DNS names can be resolved from the S3 public DNS domain.

Private DNS

Private DNS options for VPC interface endpoints simplify routing S3 traffic over VPC endpoints and help you take advantage of the lowest-cost network path available to your application. You can use private DNS options to route Regional S3 traffic without updating your S3 clients to use the endpoint-specific DNS names of your interface endpoints, or managing DNS infrastructure. With private DNS names enabled, Regional S3 DNS queries resolve to the private IP addresses of AWS PrivateLink for the following endpoints:

- Regional bucket endpoints (for example, `s3.us-east-1.amazonaws.com`)
- Control endpoints (for example, `s3-control.us-east-1.amazonaws.com`)
- Access point endpoints (for example, `s3-accesspoint.us-east-1.amazonaws.com`)

AWS PrivateLink for Amazon S3 does not support [Using Amazon S3 dual-stack endpoints](#). If you use an S3 dual-stack DNS name as a private DNS name, your IPv6 traffic will either be dropped or, if your virtual private cloud (VPC) has an internet gateway, your IPv6 traffic will be routed over the internet gateway in your VPC.

If you have a gateway endpoint in your VPC, you can automatically route in-VPC requests over your existing S3 gateway endpoint and on-premises requests over your interface endpoint. This approach allows you to optimize your networking costs by using gateway endpoints, which are not billed, for your in-VPC traffic. Your on-premises applications can use AWS PrivateLink with the help of the inbound Resolver endpoint. Amazon provides a DNS server, called the Route 53 Resolver, for your VPC. An inbound Resolver endpoint forwards DNS queries from the on-premises network to Route 53 Resolver.

Important

To take advantage of the lowest cost network path when using **Enable private DNS only for inbound endpoints**, a gateway endpoint must be present in your VPC. The presence of a gateway endpoint helps ensure that in-VPC traffic always routes over the AWS private network when the **Enable private DNS only for inbound endpoints** option is selected.

You must maintain this gateway endpoint while you have the **Enable private DNS only for inbound endpoints** option selected. If you want to delete your gateway endpoint you must first clear **Enable private DNS only for inbound endpoints**.

If you want to update an existing interface endpoint to **Enable private DNS only for inbound endpoints**, first confirm that your VPC has an S3 gateway endpoint. For more information about gateway endpoints and managing private DNS names, see [Gateway VPC endpoints](#) and [Manage DNS names](#) respectively in the *AWS PrivateLink Guide*.

The **Enable private DNS only for inbound endpoints** option is available only for services that support gateway endpoints.

For more information about creating a VPC endpoint that uses **Enable private DNS only for inbound endpoints**, see [Create an interface endpoint](#) in the *AWS PrivateLink Guide*.

Using the VPC console

In the console you have two options: **Enable DNS name** and **Enable private DNS only for inbound endpoints**. **Enable DNS name** is an option supported by AWS PrivateLink. By using the **Enable DNS name** option, you can use Amazon's private connectivity to Amazon S3, while making requests

to the default public endpoint DNS names. When this option is enabled, customers can take advantage of the lowest cost network path available to their application.

When you enable private DNS names on an existing or new VPC interface endpoint for Amazon S3, the **Enable private DNS only for inbound endpoints** option is selected by default. If this option is selected, your applications use only interface endpoints for your on-premises traffic. This in-VPC traffic automatically uses the lower-cost gateway endpoints. Alternatively, you can clear **Enable private DNS only for inbound endpoints** to route all S3 requests over your interface endpoint.

Using the AWS CLI

If you don't specify a value for `PrivateDnsOnlyForInboundResolverEndpoint`, it will default to `true`. However, before your VPC applies your settings, it performs a check to make sure that you have a gateway endpoint present in the VPC. If a gateway endpoint is present in the VPC, the call succeeds. If not, you will see the following error message:

To set `PrivateDnsOnlyForInboundResolverEndpoint` to `true`, the VPC `vpce_id` must have a gateway endpoint for the service.

For a new VPC Interface endpoint

Use the `private-dns-enabled` and `dns-options` attributes to enable private DNS through the command line. The `PrivateDnsOnlyForInboundResolverEndpoint` option in the `dns-options` attribute must be set to `true`. Replace the *user input placeholders* with your own information.

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name s3-service-name \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--private-dns-enabled \
--ip-address-type ip-address-type \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true \
--security-group-ids client-sg-id
```

For an existing VPC endpoint

If you want to use private DNS for an existing VPC endpoint, use the following example command and replace the *user input placeholders* with your own information.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=false
```

If you want to update an existing VPC endpoint to enable private DNS only for the Inbound Resolver, use the following example and replace the sample values with your own.

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-id \
--private-dns-enabled \
--dns-options PrivateDnsOnlyForInboundResolverEndpoint=true
```

Accessing buckets, access points, and Amazon S3 Control API operations from S3 interface endpoints

You can use the AWS CLI or AWS SDKs to access buckets, S3 access points, and Amazon S3 Control API operations through S3 interface endpoints.

The following image shows the VPC console **Details** tab, where you can find the DNS name of a VPC endpoint. In this example, the *VPC endpoint ID (vpce-id)* is `vpce-0e25b8cdd720f900e` and the *DNS name* is `*.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com`.

Details	Subnets	Security Groups	Policy	Notifications	Tags	VPC ID	vpc-0c0ccb9d87b1734bd VPCStack VPC
Endpoint ID	vpce-0e25b8cdd720f900e					Status message	
Status	available					Service name	com.amazonaws.us-east-1.s3
Creation time	January 8, 2021 at 1:30:11 AM UTC-8					DNS names	*.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com (Z7HUB22UULQXV)
Endpoint type	Interface						

When using the DNS name to access a resource, replace ***** with the appropriate value. The appropriate values to use in place of ***** are as follows:

- bucket
- accesspoint
- control

For example, to access a bucket, use a *DNS name* like this:

bucket.vpce-0e25b8cdd720f900e-argc85vg.s3.us-east-1.vpce.amazonaws.com

For examples of how to use DNS names to access buckets, access points, and Amazon S3 Control API operations, see the following sections of [AWS CLI examples](#) and [AWS SDK examples](#).

For more information about how to view your endpoint-specific DNS names, see [Viewing endpoint service private DNS name configuration](#) in the *VPC User Guide*.

AWS CLI examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Use an endpoint URL to list objects in your bucket

In the following example, replace the bucket name `my-bucket`, Region `us-east-1`, and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` with your own information.

```
aws s3 ls s3://my-bucket/ --region us-east-1 --endpoint-url  
https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

Example: Use an endpoint URL to list objects from an access point

- **Method 1 – Using the Amazon Resource Name (ARN) of the access point with the access point endpoint**

Replace the ARN `us-east-1:123456789012:accesspoint/accesspointname`, the Region `us-east-1`, and the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` with your own information.

```
aws s3api list-objects-v2 --bucket arn:aws:s3:us-east-1:123456789012:accesspoint/accesspointexamplename --region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

If you can't run the command successfully, update your AWS CLI to the latest version and try again. For more information on the update instructions, see [Installing or updating the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

- **Method 2 – Using the alias of the access point with the regional bucket endpoint**

In the following example, replace the access point alias

accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias, the Region **us-east-1**, and the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** with your own information.

```
aws s3api list-objects-v2 --  
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias  
--region us-east-1 --endpoint-url https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

- **Method 3 – Using the alias of the access point with the access point endpoint**

First, to construct an S3 endpoint with the bucket included as part of the hostname, set the addressing style to virtual for aws s3api to use. For more information about AWS configure, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

```
aws configure set default.s3.addressing_style virtual
```

Then, in the following example, replace the access point alias

accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias, the Region **us-east-1**, and the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** with your own information. For more information about access point alias, see [Access point aliases](#).

```
aws s3api list-objects-v2 --  
bucket accesspointexamplename-8tyekmigicmhun8n9kwpfur39dnw4use1a-s3alias --
```

```
region us-east-1 --endpoint-url https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com
```

Example: Use an endpoint URL to list jobs with an S3 control API operation

In the following example, replace the Region *us-east-1*, the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com*, and the account ID *12345678* with your own information.

```
aws s3control --region us-east-1 --endpoint-url  
https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com list-jobs --  
account-id 12345678
```

AWS SDK examples

To access S3 buckets, S3 access points, or Amazon S3 Control API operations through S3 interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then configure your clients to use an endpoint URL for accessing a bucket, access point, or Amazon S3 Control API operations through S3 interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
s3_client = session.client(  
    service_name='s3',  
    region_name='us-east-1',  
    endpoint_url='https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'  
)
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
ap_client = session.client(  
    service_name='s3',
```

```
region_name='us-east-1',
endpoint_url='https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-
east-1.vpce.amazonaws.com'
)
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the Region *us-east-1* and VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
control_client = session.client(
service_name='s3control',
region_name='us-east-1',
endpoint_url='https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com'
```

SDK for Java 1.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* with your own information.

```
// bucket client
final AmazonS3 s3 = AmazonS3ClientBuilder.standard().withEndpointConfiguration(
    new AwsClientBuilder.EndpointConfiguration(
        "https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
        Regions.DEFAULT_REGION.getName()
    )
).build();
List<Bucket> buckets = s3.listBuckets();
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID *vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com* and ARN *us-east-1:123456789012:accesspoint/prod* with your own information.

```
// accesspoint client
final AmazonS3 s3accesspoint =
    AmazonS3ClientBuilder.standard().withEndpointConfiguration(
```

```
new AwsClientBuilder.EndpointConfiguration(
    "https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
    Regions.DEFAULT_REGION.getName()
)
).build();
ObjectListing objects = s3accesspoint.listObjects("arn:aws:s3:us-east-1:123456789012:accesspoint/prod");
```

Example: Use an endpoint URL to access an Amazon S3 Control API operation

In the following example, replace the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** with your own information.

```
// control client
final AWSS3Control s3control =
    AWSS3ControlClient.builder().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
            "https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com",
            Regions.DEFAULT_REGION.getName()
        )
    ).build();
final ListJobsResult jobs = s3control.listJobs(new ListJobsRequest());
```

SDK for Java 2.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the VPC endpoint ID **vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com** and the Region **Region.US_EAST_1** with your own information.

```
// bucket client
Region region = Region.US_EAST_1;
S3Client s3Client = S3Client.builder().region(region)

.endpointOverride(URI.create("https://bucket.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com")
    .build()
```

Example: Use an endpoint URL to access an S3 access point

In the following example, replace the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` and the Region `Region.US_EAST_1` with your own information.

```
// accesspoint client
Region region = Region.US_EAST_1;
S3Client s3Client = S3Client.builder().region(region)

.endpointOverride(URI.create("https://accesspoint.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
.build()
```

Example: Use an endpoint URL to access the Amazon S3 Control API

In the following example, replace the VPC endpoint ID `vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com` and the Region `Region.US_EAST_1` with your own information.

```
// control client
Region region = Region.US_EAST_1;
S3ControlClient s3ControlClient = S3ControlClient.builder().region(region)

.endpointOverride(URI.create("https://control.vpce-1a2b3c4d-5e6f.s3.us-east-1.vpce.amazonaws.com"))
.build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for Amazon S3, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public Amazon S3 DNS domain.

Using interface endpoints to access Amazon S3 without a gateway endpoint or an internet gateway in the VPC

Interface endpoints in your VPC can route both in-VPC applications and on-premises applications to Amazon S3 over the Amazon network, as illustrated in the following diagram.

The diagram illustrates the following:

- Your on-premises network uses AWS Direct Connect or AWS VPN to connect to VPC A.
- Your applications on-premises and in VPC A use endpoint-specific DNS names to access Amazon S3 through the S3 interface endpoint.
- On-premises applications send data to the interface endpoint in the VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- In-VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.

Using gateway endpoints and interface endpoints together in the same VPC to access Amazon S3

You can create interface endpoints and retain the existing gateway endpoint in the same VPC, as the following diagram shows. By taking this approach, you allow in-VPC applications to continue accessing Amazon S3 through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access Amazon S3. To access Amazon S3 this way, you must update your on-premises applications to use endpoint-specific DNS names for Amazon S3.

The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to Amazon S3 over the AWS network.
- Using default Regional Amazon S3 names, in-VPC applications send data to the gateway endpoint that connects to Amazon S3 over the AWS network.

For more information about gateway endpoints, see [Gateway VPC endpoints](#) in the *VPC User Guide*.

Creating a VPC endpoint policy for Amazon S3

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon S3. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

You can also use Amazon S3 bucket policies to restrict access to specific buckets from a specific VPC endpoint by using the `aws:sourceVpc` condition in your bucket policy. The following examples show policies that restrict access to a bucket or to an endpoint.

Topics

- [Example: Restricting access to a specific bucket from a VPC endpoint](#)

- [Example: Restricting access to buckets in a specific account from a VPC endpoint](#)
- [Example: Restricting access to a specific VPC endpoint in the S3 bucket policy](#)

Example: Restricting access to a specific bucket from a VPC endpoint

You can create an endpoint policy that restricts access to only specific Amazon S3 buckets. This type of policy is useful if you have other AWS services in your VPC that use buckets. The following bucket policy restricts access to only the *amzn-s3-demo-bucket1*. To use this endpoint policy, replace *amzn-s3-demo-bucket1* with the name of your bucket.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909151",  
    "Statement": [  
        { "Sid": "Access-to-specific-bucket-only",  
          "Principal": "*",  
          "Action": [  
              "s3:GetObject",  
              "s3:PutObject"  
            ],  
          "Effect": "Allow",  
          "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket1",  
                      "arn:aws:s3:::amzn-s3-demo-bucket1/*"]  
        }  
    ]  
}
```

Example: Restricting access to buckets in a specific account from a VPC endpoint

You can create an endpoint policy that restricts access to only the S3 buckets in a specific AWS account. To prevent clients within your VPC from accessing buckets that you don't own, use the following statement in your endpoint policy. The following example statement creates a policy that restricts access to resources owned by a single AWS account ID, *111122223333*.

```
{  
    "Statement": [  
        {  
            "Sid": "Access-to-bucket-in-specific-account-only",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject",  
                "s3:PutObject"  
            ],  
            "Effect": "Allow",  
            "Resource": ["arn:aws:s3:::111122223333/*"]  
        }  
    ]  
}
```

```
        "s3:PutObject"
    ],
    "Effect": "Deny",
    "Resource": "arn:aws:s3:::*",
    "Condition": {
        "StringNotEquals": {
            "aws:ResourceAccount": "111122223333"
        }
    }
}
]
```

Note

To specify the AWS account ID of the resource being accessed, you can use either the `aws:ResourceAccount` or the `s3:ResourceAccount` key in your IAM policy. However, be aware that some AWS services rely on access to AWS managed buckets. Therefore, using the `aws:ResourceAccount` or `s3:ResourceAccount` key in your IAM policy might also affect access to these resources.

Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

Example: Restricting access to a specific VPC endpoint in the S3 bucket policy

The following Amazon S3 bucket policy allows access to a specific bucket, `amzn-s3-demo-bucket2`, from only the VPC endpoint `vpce-1a2b3c4d`. The policy denies all access to the bucket if the specified endpoint is not being used. The `aws:sourceVpc` condition specifies the endpoint and doesn't require an Amazon Resource Name (ARN) for the VPC endpoint resource, only the endpoint ID. To use this bucket policy, replace `amzn-s3-demo-bucket2` and `vpce-1a2b3c4d` with your bucket name and endpoint.

Important

- When applying the following Amazon S3 bucket policy to restrict access to only certain VPC endpoints, you might block your access to the bucket without intending to do so. Bucket policies that are intended to specifically limit bucket access to connections originating from your VPC endpoint can block all connections to the bucket. For

information about how to fix this issue, see [My bucket policy has the wrong VPC or VPC endpoint ID. How can I fix the policy so that I can access the bucket?](#) in the *Support Knowledge Center*.

- Before using the following example policy, replace the VPC endpoint ID with an appropriate value for your use case. Otherwise, you won't be able to access your bucket.
- This policy disables *console* access to the specified bucket, because console requests don't originate from the specified VPC endpoint.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1415115909152",  
    "Statement": [  
        { "Sid": "Access-to-specific-VPCE-only",  
            "Principal": "*",  
            "Action": "s3:*",  
            "Effect": "Deny",  
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket2",  
                        "arn:aws:s3:::amzn-s3-demo-bucket2/*"],  
            "Condition": {"StringNotEquals": {"aws:sourceVpce": "vpce-1a2b3c4d"} }  
        }  
    ]  
}
```

For more policy examples, see [Endpoints for Amazon S3](#) in the *VPC User Guide*.

For more information about VPC connectivity, see [Network-to-VPC connectivity options](#) in the AWS whitepaper [Amazon Virtual Private Cloud Connectivity Options](#).

Compliance validation for Amazon S3

The security and compliance of Amazon S3 is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry Data Security Standard (PCI DSS)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at [AWS Services in Scope by Compliance Program](#).

Third-party audit reports are available for you to download using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

For more information about AWS compliance programs, see [AWS Compliance Programs](#).

Your compliance responsibility when using Amazon S3 is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. If your use of Amazon S3 is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- [Security and Compliance Quick Start Guides](#) that discuss architectural considerations and steps for deploying security- and compliance-focused baseline environments on AWS.
- [Architecting for HIPAA Security and Compliance](#) outlines how companies use AWS to help them meet HIPAA requirements.
- [AWS Compliance Resources](#) provide several different workbooks and guides that might apply to your industry and location.
- [AWS Config](#) can be used to assess how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) provides you with a comprehensive view of your security state within AWS and helps you check your compliance with security industry standards and best practices.
- [Locking objects with Object Lock](#) can help you meet technical requirements of financial services regulators (such as the SEC, FINRA, and CFTC) that require write once, read many (WORM) data storage for certain types of books and records information.

- [Cataloging and analyzing your data with S3 Inventory](#) can help you audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs.

Resilience in Amazon S3

The AWS global infrastructure is built around Regions and Availability Zones. AWS Regions provide multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking. These Availability Zones offer you an effective way to design and operate applications and databases. They are more highly available, fault tolerant, and scalable than traditional single data center infrastructures or multi-data center infrastructures. If you specifically need to replicate your data over greater geographic distances, you can use [Replicating objects within and across Regions](#), which enables automatic, asynchronous copying of objects across buckets in different AWS Regions.

Each AWS Region has multiple Availability Zones. You can deploy your applications across multiple Availability Zones in the same Region for fault tolerance and low latency. Availability Zones are connected to each other with fast, private fiber-optic networking, enabling you to easily architect applications that automatically fail over between Availability Zones without interruption.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](#).

In addition to the AWS global infrastructure, Amazon S3 offers several features to help support your data resiliency and backup needs.

Lifecycle configuration

A lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. With lifecycle configuration rules, you can tell Amazon S3 to transition objects to less expensive storage classes, archive them, or delete them. For more information, see [Managing the lifecycle of objects](#).

Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements

that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see [Locking objects with Object Lock](#).

Storage classes

Amazon S3 offers a range of storage classes to choose from depending on the requirements of your workload. The S3 Standard-IA and S3 One Zone-IA storage classes are designed for data you access about once a month and need milliseconds access. The S3 Glacier Instant Retrieval storage class is designed for long-lived archive data accessed with milliseconds access that you access about once a quarter. For archive data that does not require immediate access, such as backups, you can use the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Understanding and managing Amazon S3 storage classes](#).

The following security best practices also address resilience:

- [Enable versioning](#)
- [Consider Amazon S3 cross-region replication](#)
- [Identify and audit all your Amazon S3 buckets](#)

Encryption of Amazon S3 backups

If you are storing backups using Amazon S3, the encryption of your backups depends on the configuration of those buckets. Amazon S3 provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The default encryption supports keys stored in AWS KMS (SSE-KMS). For more information, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

For more information about Versioning and Object Lock, see the following topics: [Retaining multiple versions of objects with S3 Versioning](#) [Locking objects with Object Lock](#)

Infrastructure security in Amazon S3

As a managed service, Amazon S3 is protected by the AWS global network security procedures that are described in the security pillar of the [AWS Well-Architected Framework](#).

Access to Amazon S3 via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend also supporting TLS 1.3. (For more information about this recommendation, see [Faster AWS cloud connections with TLS 1.3](#) on the *AWS Security Blog*.) Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Additionally, requests must be signed using AWS Signature V4 or AWS Signature V2, requiring valid credentials to be provided.

These APIs are callable from any network location. However, Amazon S3 does support resource-based access policies, which can include restrictions based on the source IP address. You can also use Amazon S3 bucket policies to control access to buckets from specific virtual private cloud (VPC) endpoints, or specific VPCs. Effectively, this isolates network access to a given Amazon S3 bucket from only the specific VPC within the AWS network. For more information, see [Controlling access from VPC endpoints with bucket policies](#).

The following security best practices also address infrastructure security in Amazon S3:

- [Consider VPC endpoints for Amazon S3 access](#)
- [Identify and audit all your Amazon S3 buckets](#)

Configuration and vulnerability analysis in Amazon S3

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- [Compliance validation for Amazon S3](#)
- [Shared Responsibility Model](#)
- [Amazon Web Services: Overview of Security Processes](#)

The following security best practices also address configuration and vulnerability analysis in Amazon S3:

- [Identify and audit all your Amazon S3 buckets](#)
- [Enable AWS Config](#)

Access management

Amazon S3 provides a variety of access management tools. The following is a list of these features and tools. You do not need all of these access management tools, but you must use one or more to grant access to your Amazon S3 buckets, objects, and other [S3 resources](#). Proper application of these tools can help make sure that your resources are accessible only to the intended users.

The most commonly used access management tool is an *access policy*. An access policy can be a *resource-based policy* that is attached to an AWS resource, such as a bucket policy for a bucket. An access policy can also be an *identity-based policy* that is attached to an AWS Identity and Access Management (IAM) identity, such as an IAM user, group, or role. An access policy describes who has access to what things. Write an access policy to grant AWS accounts and IAM users, groups, and roles permission to perform operations on a resource. For example, you can grant PUT Object permission to another AWS account so that the other account can upload objects to your bucket.

The following are the access management tools available in Amazon S3. For a more comprehensive guide on Amazon S3 access control, see [Access control in Amazon S3](#).

Bucket policy

An Amazon S3 bucket policy is a JSON-formatted [AWS Identity and Access Management \(IAM\) resource-based policy](#) that is attached to a particular bucket. Use bucket policies to grant other

AWS accounts or IAM identities permissions for the bucket and the objects in it. Many S3 access management use cases can be met by using a bucket policy. With bucket policies, you can personalize bucket access to help make sure that only the identities that you have approved can access resources and perform actions within them. For more information, see [Bucket policies for Amazon S3](#).

Identity-based policy

An identity-based or IAM user policy is a type of [AWS Identity and Access Management \(IAM\) policy](#). An identity-based policy is a JSON-formatted policy that is attached to IAM users, groups, or roles in your AWS account. You can use identity-based policies to grant an IAM identity access to your buckets or objects. You can create IAM users, groups, and roles in your account and attach access policies to them. You can then grant access to AWS resources, including Amazon S3 resources. For more information, see [Identity-based policies for Amazon S3](#).

S3 Access Grants

Use S3 Access Grants to create access grants to your Amazon S3 data for both identities in corporate identity directories, such as Active Directory, and to AWS Identity and Access Management (IAM) identities. S3 Access Grants helps you manage data permissions at scale. Additionally, S3 Access Grants logs end-user identity and the application used to access the S3 data in AWS CloudTrail. This provides a detailed audit history down to the end-user identity for all access to the data in your S3 buckets. For more information, see [Managing access with S3 Access Grants](#).

Access Points

Amazon S3 Access Points simplifies managing data access at scale for applications that use shared datasets on S3. Access Points are named network endpoints that are attached to a bucket. You can use access points to perform S3 object operations at scale, such as uploading and retrieving objects. A bucket can have up to 10,000 access points attached, and for each access point, you can enforce distinct permissions and network controls to give you detailed control over access to your S3 objects. S3 Access Points can be associated with buckets in the same account or in another trusted account. Access Points policies are resource-based policies that are evaluated in conjunction with the underlying bucket policy. For more information, see [Managing access to shared datasets with access points](#).

Access control list (ACL)

An ACL is a list of grants identifying the grantee and the permission granted. ACLs grant basic read or write permissions to other AWS accounts. ACLs use an Amazon S3-specific XML schema. An ACL is a type of [AWS Identity and Access Management \(IAM\) policy](#). An object ACL is used to manage access to an object, and a bucket ACL is used to manage access to a bucket. With bucket policies, there is a single policy for the entire bucket, but object ACLs are specified for each object. We recommend that you keep ACLs turned off, except in unusual circumstances where you must individually control access for each object. For more information about using ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Warning

The majority of modern use cases in Amazon S3 do not require the use of ACLs.

Object Ownership

To manage access to your objects, you must be the owner of the object. You can use the Object Ownership bucket-level setting to control ownership of objects uploaded to your bucket. Also, use Object Ownership to turn on ACLs. By default, Object Ownership is set to the *Bucket owner enforced setting* and all ACLs are turned off. When ACLs are turned off, the bucket owner owns all of the objects in the bucket and exclusively manages access to data. To manage access, the bucket owner uses policies or another access management tool, excluding ACLs. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

For a more comprehensive guide on Amazon S3 access control and additional best practices, see [Access control in Amazon S3](#).

Data protection in Amazon S3

In addition to the resilience offered by the AWS global infrastructure, Amazon S3 offers a number of features to help protect your data against accidental deletions or Regional failures.

S3 Replication

You can use live replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket. To enable failover controls, you can configure replication to be two-way (bidirectional) so that your source and destination buckets can be kept in sync during a Regional failure. For more information, see [the section called “Replicating objects within and across Regions”](#).

Multi-Region Access Points and failover controls

Amazon S3 Multi-Region Access Points provide a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provide built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint use [AWS Global Accelerator](#) to automatically route over the AWS global network to the closest-proximity S3 bucket with an active routing status. For more information about Multi-Region Access Points, see [the section called “Managing multi-region traffic”](#).

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover. If you have S3 Cross-Region Replication (CRR) enabled with

two-way replication rules, you can keep your buckets synchronized during a failover. For more information about failover controls, see [the section called “Failover configuration”](#).

S3 Versioning

Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

S3 Object Lock

You can use S3 Object Lock to store objects using a *write once, read many* (WORM) model. Using S3 Object Lock, you can prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. S3 Object Lock enables you to meet regulatory requirements that require WORM storage or simply to add an additional layer of protection against object changes and deletion. For more information, see [Locking objects with Object Lock](#).

AWS Backup

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan. For more information, see [the section called “Backing up your data”](#).

For a tutorial on using some of these features together to protect your data, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

Important

In addition to using the preceding features to protect your data, we recommend reviewing the recommendations in [the section called “Security best practices”](#).

Topics

- [Replicating objects within and across Regions](#)

- [Managing multi-Region traffic with Multi-Region Access Points](#)
- [Retaining multiple versions of objects with S3 Versioning](#)
- [Locking objects with Object Lock](#)
- [Backing up your Amazon S3 data](#)

Replicating objects within and across Regions

You can use replication to enable automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. You can replicate objects to a single destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Regions or within the same Region as the source bucket.

There are two types of replication: *live replication* and *on-demand replication*.

- **Live replication – To automatically replicate new and updated objects** as they are written to the source bucket, use live replication. Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use on-demand replication.
- **On-demand replication – To replicate existing objects** from the source bucket to one or more destination buckets on demand, use S3 Batch Replication. For more information about replicating existing objects, see [When to use S3 Batch Replication](#).

There are two forms of live replication: *Cross-Region Replication (CRR)* and *Same-Region Replication (SRR)*.

- **Cross-Region Replication (CRR)** – You can use CRR to replicate objects across Amazon S3 buckets in different AWS Regions. For more information about CRR, see [the section called "When to use Cross-Region Replication"](#).
- **Same-Region Replication (SRR)** – You can use SRR to copy objects across Amazon S3 buckets in the same AWS Region. For more information about SRR, see [the section called "When to use Same-Region Replication"](#).

Topics

- [Troubleshooting replication](#)
- [Monitoring replication with metrics, event notifications, and statuses](#)

Why use replication?

Replication can help you do the following:

- **Replicate objects while retaining metadata** – You can use replication to make copies of your objects that retain all metadata, such as the original object creation times and version IDs. This capability is important if you must ensure that your replica is identical to the source object.
- **Replicate objects into different storage classes** – You can use replication to directly put objects into S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or another storage class in the destination buckets. You can also replicate your data to the same storage class and use lifecycle configurations on the destination buckets to move your objects to a colder storage class as they age.
- **Maintain object copies under different ownership** – Regardless of who owns the source object, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. This is referred to as the *owner override* option. You can use this option to restrict access to object replicas.
- **Keep objects stored over multiple AWS Regions** – To ensure geographic differences in where your data is kept, you can set multiple destination buckets across different AWS Regions. This feature might help you meet certain compliance requirements.
- **Replicate objects within 15 minutes** – To replicate your data in the same AWS Region or across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3

RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#).

 **Note**

S3 RTC does not apply to Batch Replication. Batch Replication is an on-demand replication job, and can be tracked with S3 Batch Operations. For more information, see [Tracking job status and completion reports](#).

- **Sync buckets, replicate existing objects, and replicate previously failed or replicated objects** – To sync buckets and replicate existing objects, use Batch Replication as an on-demand replication action. For more information about when to use Batch Replication, see [When to use S3 Batch Replication](#).
- **Replicate objects and fail over to a bucket in another AWS Region** – To keep all metadata and objects in sync across buckets during data replication, use two-way replication (also known as bi-directional replication) rules before configuring Amazon S3 Multi-Region Access Point failover controls. Two-way replication rules help ensure that when data is written to the S3 bucket that traffic fails over to, that data is then replicated back to the source bucket.

When to use Cross-Region Replication

S3 Cross-Region Replication (CRR) is used to copy objects across Amazon S3 buckets in different AWS Regions. CRR can help you do the following:

- **Meet compliance requirements** – Although Amazon S3 stores your data across multiple geographically distant Availability Zones by default, compliance requirements might dictate that you store data at even greater distances. To satisfy these requirements, use Cross-Region Replication to replicate data between distant AWS Regions.
- **Minimize latency** – If your customers are in two geographic locations, you can minimize latency in accessing objects by maintaining object copies in AWS Regions that are geographically closer to your users.
- **Increase operational efficiency** – If you have compute clusters in two different AWS Regions that analyze the same set of objects, you might choose to maintain object copies in those Regions.

When to use Same-Region Replication

Same-Region Replication (SRR) is used to copy objects across Amazon S3 buckets in the same AWS Region. SRR can help you do the following:

- **Aggregate logs into a single bucket** – If you store logs in multiple buckets or across multiple accounts, you can easily replicate logs into a single, in-Region bucket. Doing so allows for simpler processing of logs in a single location.
- **Configure live replication between production and test accounts** – If you or your customers have production and test accounts that use the same data, you can replicate objects between those multiple accounts, while maintaining object metadata.
- **Abide by data sovereignty laws** – You might be required to store multiple copies of your data in separate AWS accounts within a certain Region. Same-Region Replication can help you automatically replicate critical data when compliance regulations don't allow the data to leave your country.

When to use two-way replication (bi-directional replication)

- **Build shared datasets across multiple AWS Regions** – With replica modification sync, you can easily replicate metadata changes, such as object access control lists (ACLs), object tags, or object locks, on replication objects. This two-way replication is important if you want to keep all objects and object metadata changes in sync. You can [enable replica modification sync](#) on a new or existing replication rule when performing two-way replication between two or more buckets in the same or different AWS Regions.
- **Keep data synchronized across Regions during failover** – You can synchronize data in buckets between AWS Regions by configuring two-way replication rules with S3 Cross-Region Replication (CRR) directly from a Multi-Region Access Point. To make an informed decision on when to initiate failover, you can also enable S3 replication metrics so that you can monitor the replication in Amazon CloudWatch, in S3 Replication Time Control (S3 RTC), or from the Multi-Region Access Point.
- **Make your application highly available** – Even in the event of a Regional traffic disruption, you can use two-way replication rules to keep all metadata and objects in sync across buckets during data replication.

When to use S3 Batch Replication

Batch Replication replicates existing objects to different buckets as an on-demand option. Unlike live replication, these jobs can be run as needed. Batch Replication can help you do the following:

- **Replicate existing objects** – You can use Batch Replication to replicate objects that were added to the bucket before Same-Region Replication or Cross-Region Replication were configured.
- **Replicate objects that previously failed to replicate** – You can filter a Batch Replication job to attempt to replicate objects with a replication status of **FAILED**.
- **Replicate objects that were already replicated** – You might be required to store multiple copies of your data in separate AWS accounts or AWS Regions. Batch Replication can replicate existing objects to newly added destinations.
- **Replicate replicas of objects that were created from a replication rule** – Replication configurations create replicas of objects in destination buckets. Replicas of objects can be replicated only with Batch Replication.

Workload requirements and live replication

Depending on your workload requirements, some types of live replication will be better suited to your use case than others. Use the following table to determine which type of replication to use for your situation, and whether to use S3 Replication Time Control (S3 RTC) for your workload. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement, or SLA). For more information, see [the section called “Using S3 Replication Time Control”](#).

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
Replicate objects between different AWS accounts	Yes	Yes	Yes
Replicate objects within the same AWS Region within	No	No	Yes

Workload requirement	S3 RTC (15-minute SLA)	Cross-Region Replication (CRR)	Same-Region Replication (SRR)
24-48 hours (not SLA backed)			
Replicate objects between different AWS Regions within 24-48 hours (not SLA backed)	No	Yes	No
Predictable replication time: Backed by SLA to replicate 99.9 percent of objects within 15 minutes	Yes	No	No

What does Amazon S3 replicate?

Amazon S3 replicates only specific items in buckets that are configured for replication.

Topics

- [What is replicated with replication configurations?](#)
- [What isn't replicated with replication configurations?](#)

What is replicated with replication configurations?

By default, Amazon S3 replicates the following:

- Objects created after you add a replication configuration.
- Unencrypted objects.
- Objects encrypted using customer provided keys (SSE-C), objects encrypted at rest under an Amazon S3 managed key (SSE-S3) or a KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see [the section called “Replicating encrypted objects”](#).

- Object metadata from the source objects to the replicas. For information about replicating metadata from the replicas to the source objects, see [Replicating metadata changes with replica modification sync](#).
- Only objects in the source bucket for which the bucket owner has permissions to read objects and access control lists (ACLs).

For more information about resource ownership, see [Amazon S3 bucket and object ownership](#).

- Object ACL updates, unless you direct Amazon S3 to change the replica ownership when source and destination buckets aren't owned by the same accounts.

For more information, see [Changing the replica owner](#).

It can take a while until Amazon S3 can bring the two ACLs in sync. This change in ownership applies only to objects created after you add a replication configuration to the bucket.

- Object tags, if there are any.
- S3 Object Lock retention information, if there is any.

When Amazon S3 replicates objects that have retention information applied, it applies those same retention controls to your replicas, overriding the default retention period configured on your destination buckets. If you don't have retention controls applied to the objects in your source bucket, and you replicate into destination buckets that have a default retention period set, the destination bucket's default retention period is applied to your object replicas. For more information, see [Locking objects with Object Lock](#).

How delete operations affect replication

If you delete an object from the source bucket, the following actions occur by default:

- If you make a DELETE request without specifying an object version ID, Amazon S3 adds a delete marker. Amazon S3 deals with the delete marker as follows:
 - If you are using the latest version of the replication configuration (that is, you specify the `Filter` element in a replication configuration rule), Amazon S3 does not replicate the delete marker by default. However, you can add *delete marker replication* to non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).
 - If you don't specify the `Filter` element, Amazon S3 assumes that the replication configuration is version V1, and it replicates delete markers that resulted from user actions.

However, if Amazon S3 deletes an object due to a lifecycle action, the delete marker is not replicated to the destination buckets.

- If you specify an object version ID to delete in a DELETE request, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination buckets. In other words, it doesn't delete the same object version from the destination buckets. This protects data from malicious deletions.

What isn't replicated with replication configurations?

By default, Amazon S3 doesn't replicate the following:

- Objects in the source bucket that are replicas that were created by another replication rule. For example, suppose you configure replication where bucket A is the source and bucket B is the destination. Now suppose that you add another replication configuration where bucket B is the source and bucket C is the destination. In this case, objects in bucket B that are replicas of objects in bucket A are not replicated to bucket C.

To replicate objects that are replicas, use Batch Replication. Learn more about configuring Batch Replication at [Replicating existing objects](#).

- Objects in the source bucket that have already been replicated to a different destination. For example, if you change the destination bucket in an existing replication configuration, Amazon S3 won't replicate the objects again.

To replicate previously replicated objects, use Batch Replication. Learn more about configuring Batch Replication at [Replicating existing objects](#).

- Batch Replication does not support re-replicating objects that were deleted with the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and initiates replication automatically to the destination. For more information about how to use Batch Copy, see, [Examples that use Batch Operations to copy objects](#).
- By default, when replicating from a different AWS account, delete markers added to the source bucket are not replicated.

For information about how to replicate delete markers, see [Replicating delete markers between buckets](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, S3 Intelligent-Tiering Archive Access, or S3 Intelligent-Tiering Deep Archive Access storage classes or tiers. You cannot replicate these objects until you restore them and copy them to a different storage class.

To learn more about S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive, see [Storage classes for rarely accessed objects](#).

To learn more about the S3 Intelligent-Tiering, see [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

- Objects in the source bucket that the bucket owner doesn't have sufficient permissions to replicate.

For information about how an object owner can grant permissions to a bucket owner, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).

- Updates to bucket-level subresources.

For example, if you change the lifecycle configuration or add a notification configuration to your source bucket, these changes are not applied to the destination bucket. This feature makes it possible to have different configurations on source and destination buckets.

- Actions performed by lifecycle configuration.

For example, if lifecycle configuration is enabled only on your source bucket, Amazon S3 creates delete markers for expired objects but doesn't replicate those markers. If you want the same lifecycle configuration applied to both the source and destination buckets, enable the same lifecycle configuration on both. For more information about lifecycle configuration, see [Managing the lifecycle of objects](#).

- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the PutObject operation. Otherwise, the objects won't be replicated. If objects are tagged after the PutObject operation, those objects also won't be replicated.

To replicate objects that have been tagged after the PutObject operation, you must use S3 Batch Replication. For more information about Batch Replication, see [Replicating existing objects](#).

Requirements and considerations for replication

Amazon S3 replication requires the following:

- The source bucket owner must have the source and destination AWS Regions enabled for their account. The destination bucket owner must have the destination Region enabled for their account.

For more information about enabling or disabling an AWS Region, see [Specify which AWS Regions your account can use in the AWS Account Management Reference Guide](#).

- Both source and destination buckets must have versioning enabled. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).
- Amazon S3 must have permissions to replicate objects from the source bucket to the destination bucket or buckets on your behalf. For more information about these permissions, see [Setting up permissions for live replication](#).
- If the owner of the source bucket doesn't own the object in the bucket, the object owner must grant the bucket owner READ and READ_ACP permissions with the object access control list (ACL). For more information, see [Access control list \(ACL\) overview](#).
- If the source bucket has S3 Object Lock enabled, the destination buckets must also have S3 Object Lock enabled.

To enable replication on a bucket that has Object Lock enabled, you must use the AWS Command Line Interface, REST API, or AWS SDKs. For more general information, see [Locking objects with Object Lock](#).

 **Note**

You must grant two new permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two new permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission, it satisfies the requirement. For more information, see [Setting up permissions for live replication](#).

For more information, see [Setting up live replication overview](#).

If you are setting the replication configuration in a *cross-account scenario*, where the source and destination buckets are owned by different AWS accounts, the following additional requirement applies:

- The owner of the destination buckets must grant the owner of the source bucket permissions to replicate objects with a bucket policy. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).
- The destination buckets cannot be configured as Requester Pays buckets. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).

Considerations for replication

Before you create a replication configuration, be aware of the following considerations.

Topics

- [Lifecycle configuration and object replicas](#)
- [Versioning configuration and replication configuration](#)
- [Using S3 Replication with S3 Intelligent-Tiering](#)
- [Logging configuration and replication configuration](#)
- [CRR and the destination Region](#)
- [S3 Batch Replication](#)
- [S3 Replication Time Control](#)

Lifecycle configuration and object replicas

The time it takes for Amazon S3 to replicate an object depends on the size of the object. For large objects, it can take several hours. Although it might take a while before a replica is available in the destination, it takes the same amount of time to create the replica as it took to create the corresponding object in the source bucket. If a lifecycle configuration is enabled on a destination bucket, the lifecycle rules honor the original creation time of the object, not when the replica became available in the destination bucket.

Replication configuration requires the bucket to be versioning-enabled. When you enable versioning on a bucket, keep the following in mind:

- If you have an object Expiration lifecycle configuration, after you enable versioning, add a NonCurrentVersionExpiration policy to maintain the same permanent delete behavior as before you enabled versioning.
- If you have a Transition lifecycle configuration, after you enable versioning, consider adding a NonCurrentVersionTransition policy.

Versioning configuration and replication configuration

Both the source and destination buckets must be versioning-enabled when you configure replication on a bucket. After you enable versioning on both the source and destination buckets and configure replication on the source bucket, you will encounter the following issues:

- If you attempt to disable versioning on the source bucket, Amazon S3 returns an error. You must remove the replication configuration before you can disable versioning on the source bucket.
- If you disable versioning on the destination bucket, replication fails. The source object has the replication status FAILED.

Using S3 Replication with S3 Intelligent-Tiering

S3 Intelligent-Tiering is a storage class that is designed to optimize storage costs by automatically moving data to the most cost-effective access tier. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

Replicating objects stored in S3 Intelligent-Tiering with S3 Batch Replication or invoking [CopyObject](#) or [UploadPartCopy](#) constitutes access. In these cases, the source objects of the copy or replication operations are tiered up.

For more information about S3 Intelligent-Tiering see, [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

Logging configuration and replication configuration

If Amazon S3 delivers logs to a bucket that has replication enabled, it replicates the log objects.

If [server access logs](#) or [AWS CloudTrail logs](#) are enabled on your source or destination bucket, Amazon S3 includes replication-related requests in the logs. For example, Amazon S3 logs each object that it replicates.

CRR and the destination Region

Amazon S3 Cross-Region Replication (CRR) is used to copy objects across S3 buckets in different AWS Regions. You might choose the Region for your destination bucket based on either your business needs or cost considerations. For example, inter-Region data transfer charges vary depending on the Regions that you choose.

Suppose that you chose US East (N. Virginia) (us-east-1) as the Region for your source bucket. If you choose US West (Oregon) (us-west-2) as the Region for your destination buckets, you pay more than if you choose the US East (Ohio) (us-east-2) Region. For pricing information, see "Data Transfer Pricing" in [Amazon S3 pricing](#).

There are no data transfer charges associated with Same-Region Replication (SRR).

S3 Batch Replication

For information about considerations for Batch Replication, see [S3 Batch Replication considerations](#).

S3 Replication Time Control

For information about best practices and considerations for S3 Replication Time Control (S3 RTC), see [Best practices and guidelines for S3 RTC](#).

Setting up live replication overview

Note

Objects that existed before you set up replication aren't replicated automatically. In other words, Amazon S3 doesn't replicate objects retroactively. To replicate objects that were created before your replication configuration, use S3 Batch Replication. For more information about configuring Batch Replication, see [Replicating existing objects](#).

To enable live replication—Same-Region Replication (SRR) or Cross-Region Replication (CRR)—add a replication configuration to your source bucket. This configuration tells Amazon S3 to replicate objects as specified. In the replication configuration, you must provide the following:

- **The destination buckets** – The bucket or buckets where you want Amazon S3 to replicate the objects.

- **The objects that you want to replicate** – You can replicate all objects in the source bucket or a subset of objects. You identify a subset by providing a [key name prefix](#), one or more object tags, or both in the configuration.

For example, if you configure a replication rule to replicate only objects with the key name prefix Tax/, Amazon S3 replicates objects with keys such as Tax/doc1 or Tax/doc2. But it doesn't replicate objects with the key Legal/doc3. If you specify both a prefix and one or more tags, Amazon S3 replicates only objects that have the specific key prefix and tags.

- **An AWS Identity and Access Management (IAM) role** – Amazon S3 assumes this IAM role to replicate objects on your behalf. For more information about creating this IAM role and managing permissions, see [Setting up permissions for live replication](#).

In addition to these minimum requirements, you can choose the following options:

- **Replica storage class** – By default, Amazon S3 stores object replicas using the same storage class as the source object. You can specify a different storage class for the replicas.
- **Replica ownership** – Amazon S3 assumes that an object replica continues to be owned by the owner of the source object. So when it replicates objects, it also replicates the corresponding object access control list (ACL) or S3 Object Ownership setting. If the source and destination buckets are owned by different AWS accounts, you can configure replication to change the owner of a replica to the AWS account that owns the destination bucket. For more information, see [the section called "Changing the replica owner"](#).

You can configure replication by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API. For detailed walkthroughs of how to set up replication, see [the section called "Replication walkthroughs"](#).

Amazon S3 provides REST API operations to support setting up replication rules. For more information, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PutBucketReplication](#)
- [GetBucketReplication](#)
- [DeleteBucketReplication](#)

Topics

- [Replication configuration file elements](#)

- [Setting up permissions for live replication](#)
- [Examples for configuring live replication](#)

Replication configuration file elements

Amazon S3 stores a replication configuration as XML. If you're configuring replication programmatically through the Amazon S3 REST API, you specify the various elements of your replication configuration in this XML file. If you're configuring replication through the AWS Command Line Interface (AWS CLI), you specify your replication configuration using JSON format. For JSON examples, see the walkthroughs in [the section called "Replication walkthroughs"](#).

Note

The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see [GetBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, see [Backward compatibility considerations](#) for backward compatibility considerations.

In the replication configuration XML file, you must specify an AWS Identity and Access Management (IAM) role and one or more rules, as shown in the following example:

```
<ReplicationConfiguration>
  <Role>IAM-role-ARN</Role>
  <Rule>
    ...
  </Rule>
  <Rule>
    ...
  </Rule>
  ...
</ReplicationConfiguration>
```

Amazon S3 can't replicate objects without your permission. You grant permissions to Amazon S3 with the IAM role that you specify in the replication configuration. Amazon S3 assumes this IAM role to replicate objects on your behalf. You must grant the required permissions to the IAM role first. For more information about managing permissions, see [Setting up permissions for live replication](#).

You add only one rule in a replication configuration in the following scenarios:

- You want to replicate all objects.
- You want to replicate only one subset of objects. You identify the object subset by adding a filter in the rule. In the filter, you specify an object key prefix, tags, or a combination of both to identify the subset of objects that the rule applies to. The filters target objects that match the exact values that you specify.

If you want to replicate different subsets of objects, you add multiple rules in a replication configuration. In each rule, you specify a filter that selects a different subset. For example, you might choose to replicate objects that have either tax/ or document/ key prefixes. To do this, you add two rules, one that specifies the tax/ key prefix filter and another that specifies the document/ key prefix. For more information about object key prefixes, see [Organizing objects using prefixes](#).

The following sections provide additional information.

Topics

- [Basic rule configuration](#)
- [Optional: Specifying a filter](#)
- [Additional destination configurations](#)
- [Example replication configurations](#)
- [Backward compatibility considerations](#)

Basic rule configuration

Each rule must include the rule's status and priority. The rule must also indicate whether to replicate delete markers.

- The <Status> element indicates whether the rule is enabled or disabled by using the values Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform the actions specified in the rule.
- The <Priority> element indicates which rule has precedence whenever two or more replication rules conflict. Amazon S3 attempts to replicate objects according to all replication rules. However, if there are two or more rules with the same destination bucket, then objects are replicated according to the rule with the highest priority. The higher the number, the higher the priority.
- The <DeleteMarkerReplication> element indicates whether to replicate delete markers by using the values Enabled or Disabled.

In the <Destination> element configuration, you must provide the name of the destination bucket or buckets where you want Amazon S3 to replicate objects.

The following example shows the minimum requirements for a V2 rule. For backward compatibility, Amazon S3 continues to support the XML V1 format. For more information, see [Backward compatibility considerations](#).

```
...
<Rule>
    <ID>Rule-1</ID>
    <Status>Enabled-or-Disabled</Status>
    <Filter>
        <Prefix></Prefix>
    </Filter>
    <Priority>integer</Priority>
    <DeleteMarkerReplication>
        <Status>Enabled-or-Disabled</Status>
    </DeleteMarkerReplication>
    <Destination>
        <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
</Rule>
<Rule>
    ...
</Rule>
...
...
```

You can also specify other configuration options. For example, you might choose to use a storage class for object replicas that differs from the class for the source object.

Optional: Specifying a filter

To choose a subset of objects that the rule applies to, add an optional filter. You can filter by object key prefix, object tags, or a combination of both. If you filter on both a key prefix and object tags, Amazon S3 combines the filters by using a logical AND operator. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

Filter based on object key prefix

To specify a rule with a filter based on an object key prefix, use the following XML. You can specify only one prefix per rule.

```
<Rule>
  ...
  <Filter>
    <Prefix>key-prefix</Prefix>
  </Filter>
  ...
</Rule>
...
```

Filter based on object tags

To specify a rule with a filter based on object tags, use the following XML. You can specify one or more object tags.

```
<Rule>
  ...
  <Filter>
    <And>
      <Tag>
        <Key>key1</Key>
        <Value>value1</Value>
      </Tag>
      <Tag>
        <Key>key2</Key>
        <Value>value2</Value>
      </Tag>
      ...
    </And>
  </Filter>
</Rule>
```

```
</And>
</Filter>
...
</Rule>
...
```

Filter with a key prefix and object tags

To specify a rule filter with a combination of a key prefix and object tags, use the following XML. You wrap these filters in an `<And>` parent element. Amazon S3 performs a logical AND operation to combine these filters. In other words, the rule applies to a subset of objects with both a specific key prefix and specific tags.

```
<Rule>
...
<Filter>
  <And>
    <Prefix>key-prefix</Prefix>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
    ...
  </And>
</Filter>
...
</Rule>
...
```

Note

- If you specify a rule with an empty `<Filter>` element, your rule applies to all objects in your bucket.
- When you're using tag-based replication rules with live replication, new objects must be tagged with the matching replication rule tag in the `PutObject` operation. Otherwise, the objects won't be replicated. If objects are tagged after the `PutObject` operation, those objects also won't be replicated.

To replicate objects that have been tagged after the PutObject operation, you must use S3 Batch Replication. For more information about Batch Replication, see [Replicating existing objects](#).

Additional destination configurations

In the destination configuration, you specify the bucket or buckets where you want Amazon S3 to replicate objects. You can set configurations to replicate objects from one source bucket to one or more destination buckets.

```
...
<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>
...
```

You can add the following options in the `<Destination>` element.

Topics

- [Specify storage class](#)
- [Add multiple destination buckets](#)
- [Specify different parameters for each replication rule with multiple destination buckets](#)
- [Change replica ownership](#)
- [Enable S3 Replication Time Control](#)
- [Replicate objects created with server-side encryption by using AWS KMS](#)

Specify storage class

You can specify the storage class for the object replicas. By default, Amazon S3 uses the storage class of the source object to create object replicas, as in the following example.

```
...
<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
        <StorageClass>storage-class</StorageClass>
</Destination>
```

...

Add multiple destination buckets

You can add multiple destination buckets in a single replication configuration, as follows.

```
...
<Rule>
  <ID>Rule-1</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
  </DeleteMarkerReplication>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
  </Destination>
</Rule>
<Rule>
  <ID>Rule-2</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Enabled-or-Disabled</Status>
  </DeleteMarkerReplication>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
  </Destination>
</Rule>
...
...
```

Specify different parameters for each replication rule with multiple destination buckets

When adding multiple destination buckets in a single replication configuration, you can specify different parameters for each replication rule, as follows.

```
...
<Rule>
  <ID>Rule-1</ID>
  <Status>Enabled-or-Disabled</Status>
  <Priority>integer</Priority>
  <DeleteMarkerReplication>
    <Status>Disabled</Status>
```

```
</DeleteMarkerReplication>
<Metrics>
<Status>Enabled</Status>
<EventThreshold>
<Minutes>15</Minutes>
</EventThreshold>
</Metrics>
<Destination>
<Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket1</Bucket>
</Destination>
</Rule>
<Rule>
<ID>Rule-2</ID>
<Status>Enabled-or-Disabled</Status>
<Priority>integer</Priority>
<DeleteMarkerReplication>
<Status>Enabled</Status>
</DeleteMarkerReplication>
<Metrics>
<Status>Enabled</Status>
<EventThreshold>
<Minutes>15</Minutes>
</EventThreshold>
</Metrics>
<ReplicationTime>
<Status>Enabled</Status>
<Time>
<Minutes>15</Minutes>
</Time>
</ReplicationTime>
<Destination>
<Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket2</Bucket>
</Destination>
</Rule>
...
...
```

Change replica ownership

When the source and destination buckets aren't owned by the same accounts, you can change the ownership of the replica to the AWS account that owns the destination bucket. To do so, add the `<AccessControlTranslation>` element. This element takes the value `Destination`.

...

```
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <Account>destination-bucket-owner-account-id</Account>
  <AccessControlTranslation>
    <Owner>Destination</Owner>
  </AccessControlTranslation>
</Destination>
...
...
```

If you don't add the `<AccessControlTranslation>` element to the replication configuration, the replicas are owned by the same AWS account that owns the source object. For more information, see [Changing the replica owner](#).

Enable S3 Replication Time Control

You can enable S3 Replication Time Control (S3 RTC) in your replication configuration. S3 RTC replicates most objects in seconds and 99.99 percent of objects within 15 minutes (backed by a service-level agreement).

Only a value of `<Minutes>15</Minutes>` is accepted for the `<EventThreshold>` and `<Time>` elements.

```
...
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <Metrics>
    <Status>Enabled</Status>
    <EventThreshold>
      <Minutes>15</Minutes>
    </EventThreshold>
  </Metrics>
  <ReplicationTime>
    <Status>Enabled</Status>
    <Time>
      <Minutes>15</Minutes>
    </Time>
  </ReplicationTime>
</Destination>
```

...

For more information, see [Meeting compliance requirements with S3 Replication Time Control](#). For API examples, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Replicate objects created with server-side encryption by using AWS KMS

Your source bucket might contain objects that were created with server-side encryption by using AWS Key Management Service (AWS KMS) keys (SSE-KMS). By default, Amazon S3 doesn't replicate these objects. You can optionally direct Amazon S3 to replicate these objects. To do so, first explicitly opt into this feature by adding the <SourceSelectionCriteria> element. Then provide the AWS KMS key (for the AWS Region of the destination bucket) to use for encrypting object replicas. The following example shows how to specify these elements.

```
...
<SourceSelectionCriteria>
  <SseKmsEncryptedObjects>
    <Status>Enabled</Status>
  </SseKmsEncryptedObjects>
</SourceSelectionCriteria>
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  <EncryptionConfiguration>
    <ReplicaKmsKeyID>AWS KMS key ID to use for encrypting object replicas</ReplicaKmsKeyID>
  </EncryptionConfiguration>
</Destination>
...

```

For more information, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

Example replication configurations

To get started, you can add the following example replication configurations to your bucket, as appropriate.

Important

To add a replication configuration to a bucket, you must have the `iam:PassRole` permission. This permission allows you to pass the IAM role that grants Amazon S3 replication permissions. You specify the IAM role by providing the Amazon Resource Name

(ARN) that is used in the <Role> element in the replication configuration XML. For more information, see [Granting a User Permissions to Pass a Role to an AWS service](#) in the *IAM User Guide*.

Example 1: Replication configuration with one rule

The following basic replication configuration specifies one rule. The rule specifies an IAM role that Amazon S3 can assume and a single destination bucket for object replicas. The <Status> element value of Enabled indicates that the rule is in effect.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>

    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To choose a subset of objects to replicate, you can add a filter. In the following configuration, the filter specifies an object key prefix. This rule applies to objects that have the prefix *Tax/* in their key names.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
      <Prefix>Tax/</Prefix>
    </Filter>
```

```
<Destination>
  <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>

</Rule>
</ReplicationConfiguration>
```

If you specify the `<Filter>` element, you must also include the `<Priority>` and `<DeleteMarkerReplication>` elements. In this example, the value that you set for the `<Priority>` element is irrelevant because there is only one rule.

In the following configuration, the filter specifies one prefix and two tags. The rule applies to the subset of objects that have the specified key prefix and tags. Specifically, it applies to objects that have the `Tax/` prefix in their key names and the two specified object tags. In this example, the value that you set for the `<Priority>` element is irrelevant because there is only one rule.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>

    <Filter>
      <And>
        <Prefix>Tax/</Prefix>
        <Tag>
          <Tag>
            <Key>tagA</Key>
            <Value>valueA</Value>
          </Tag>
        </Tag>
        <Tag>
          <Tag>
            <Key>tagB</Key>
            <Value>valueB</Value>
          </Tag>
        </Tag>
      </And>
    </Filter>
  </Rule>
</ReplicationConfiguration>
```

```
</Filter>

<Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
</Destination>

</Rule>
</ReplicationConfiguration>
```

You can specify a storage class for the object replicas as follows:

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <Role>arn:aws:iam::account-id:role/role-name</Role>
    <Rule>
        <Status>Enabled</Status>
        <Destination>
            <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
            <StorageClass>storage-class</StorageClass>
        </Destination>
    </Rule>
</ReplicationConfiguration>
```

You can specify any storage class that Amazon S3 supports.

Example 2: Replication configuration with two rules

Example

In the following replication configuration, the rules specify the following:

- Each rule filters on a different key prefix so that each rule applies to a distinct subset of objects. In this example, Amazon S3 replicates objects with the key names *Tax/doc1.pdf* and *Project/project1.txt*, but it doesn't replicate objects with the key name *PersonalDoc/documentA*.
- Although both rules specify a value for the *<Priority>* element, the rule priority is irrelevant because the rules apply to two distinct sets of objects. The next example shows what happens when rule priority is applied.

- The second rule specifies the S3 Standard-IA storage class for object replicas. Amazon S3 uses the specified storage class for those object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>

<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
    ...
  </Rule>
  <Rule>
    <Status>Enabled</Status>
    <Priority>2</Priority>
    <DeleteMarkerReplication>
      <Status>string</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Project</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
      <StorageClass>STANDARD_IA</StorageClass>
    </Destination>
    ...
  </Rule>
</ReplicationConfiguration>
```

Example 3: Replication configuration with two rules with overlapping prefixes

In this configuration, the two rules specify filters with overlapping key prefixes, *star/* and *starship/*. Both rules apply to objects with the key name *starship-x*. In this case, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority.

```
<ReplicationConfiguration>

<Role>arn:aws:iam::account-id:role/role-name</Role>

<Rule>
  <Status>Enabled</Status>
  <Priority>1</Priority>
  <DeleteMarkerReplication>
    <Status>string</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>star</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  </Destination>
</Rule>
<Rule>
  <Status>Enabled</Status>
  <Priority>2</Priority>
  <DeleteMarkerReplication>
    <Status>string</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>starship</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
  </Destination>
</Rule>
</ReplicationConfiguration>
```

Example 4: Example walkthroughs

For example walkthroughs, see [Examples for configuring live replication](#).

For more information about the XML structure of replication configuration, see [PutBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

Backward compatibility considerations

The latest version of the replication configuration XML format is V2. XML V2 replication configurations are those that contain the `<Filter>` element for rules, and rules that specify S3 Replication Time Control (S3 RTC).

To see your replication configuration version, you can use the `GetBucketReplication` API operation. For more information, see [GetBucketReplication](#) in the *Amazon Simple Storage Service API Reference*.

For backward compatibility, Amazon S3 continues to support the XML V1 replication configuration format. If you've used the XML V1 replication configuration format, consider the following issues that affect backward compatibility:

- The replication configuration XML V2 format includes the `<Filter>` element for rules. With the `<Filter>` element, you can specify object filters based on the object key prefix, tags, or both to scope the objects that the rule applies to. The replication configuration XML V1 format supports filtering based only on the key prefix. In that case, you add the `<Prefix>` element directly as a child element of the `<Rule>` element, as in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Role>arn:aws:iam::account-id:role/role-name</Role>
  <Rule>
    <Status>Enabled</Status>
    <Prefix>key-prefix</Prefix>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

- When you delete an object from your source bucket without specifying an object version ID, Amazon S3 adds a delete marker. If you use the replication configuration XML V1 format, Amazon S3 replicates only delete markers that result from user actions. In other words, Amazon S3 replicates the delete marker only if a user deletes an object. If an expired object is removed by Amazon S3 (as part of a lifecycle action), Amazon S3 doesn't replicate the delete marker.

In the replication configuration XML V2 format, you can enable delete marker replication for non-tag-based rules. For more information, see [Replicating delete markers between buckets](#).

Setting up permissions for live replication

When setting up live replication in Amazon S3, you must acquire the necessary permissions as follows:

- Amazon S3 needs permissions to replicate objects on your behalf. You grant these permissions by creating an AWS Identity and Access Management (IAM) role and then specifying that role in your replication configuration.
- When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also grant the source bucket owner permissions to store the replicas.

Topics

- [Creating an IAM role](#)
- [Granting permissions when the source and destination buckets are owned by different AWS accounts](#)
- [Changing replica ownership](#)
- [Granting permissions for S3 Batch Operations](#)

Creating an IAM role

By default, all Amazon S3 resources—buckets, objects, and related subresources—are private, and only the resource owner can access the resource. Amazon S3 needs permissions to read and replicate objects from the source bucket. You grant these permissions by creating an IAM role and specifying that role in your replication configuration.

This section explains the trust policy and the minimum required permissions policy that are attached to this IAM role. The example walkthroughs provide step-by-step instructions to create an IAM role. For more information, see [Examples for configuring live replication](#).

The *trust policy* identifies which principal identities can assume the IAM role. The *permissions policy* specifies which actions the IAM role can perform, on which resources, and under what conditions.

- The following example shows a *trust policy* where you identify Amazon S3 as the AWS service principal that can assume the role:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- The following example shows a *trust policy* where you identify Amazon S3 and S3 Batch Operations as service principals that can assume the role. Use this approach if you're creating a Batch Replication job. For more information, see [Create a Batch Replication job for new replication rules or destinations](#).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": [  
                    "s3.amazonaws.com",  
                    "batchoperations.s3.amazonaws.com"  
                ]  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

For more information about IAM roles, see [IAM roles](#) in the *IAM User Guide*.

- The following example shows the *permissions policy*, where you grant the IAM role permissions to perform replication tasks on your behalf. When Amazon S3 assumes the role, it has the

permissions that you specify in this policy. In this policy, *amzn-s3-demo-source-bucket* is the source bucket, and *amzn-s3-demo-destination-bucket* is the destination bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetReplicationConfiguration",  
                "s3>ListBucket"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObjectVersionForReplication",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ReplicateTags"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        }  
    ]  
}
```

The permissions policy grants permissions for the following actions:

- `s3:GetReplicationConfiguration` and `s3>ListBucket` – Permissions for these actions on the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to retrieve the replication

configuration and list the bucket content. (The current permissions model requires the s3:ListBucket permission for accessing delete markers.)

- s3:GetObjectVersionForReplication and s3:GetObjectVersionAcl – Permissions for these actions are granted on all objects to allow Amazon S3 to get a specific object version and access control list (ACL) associated with the objects.
- s3:ReplicateObject and s3:ReplicateDelete – Permissions for these actions on all objects in the *amzn-s3-demo-destination-bucket* bucket allow Amazon S3 to replicate objects or delete markers to the destination bucket. For information about delete markers, see [How delete operations affect replication](#).

 **Note**

Permissions for the s3:ReplicateObject action on the *amzn-s3-demo-destination-bucket* bucket also allow replication of metadata such as object tags and ACLs. Therefore, you don't need to explicitly grant permission for the s3:ReplicateTags action.

- s3:GetObjectVersionTagging – Permissions for this action on objects in the *amzn-s3-demo-source-bucket* bucket allow Amazon S3 to read object tags for replication. For more information about object tags, see [Categorizing your storage using tags](#). If Amazon S3 doesn't have the s3:GetObjectVersionTagging permission, it replicates the objects, but not the object tags.

For a list of Amazon S3 actions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

 **Important**

The AWS account that owns the IAM role must have permissions for the actions that it grants to the IAM role.

For example, suppose that the source bucket contains objects owned by another AWS account. The owner of the objects must explicitly grant the AWS account that owns the IAM role the required permissions through the objects' access control lists (ACLs).

Otherwise, Amazon S3 can't access the objects, and replication of the objects fails. For information about ACL permissions, see [Access control list \(ACL\) overview](#).

The permissions described here are related to the minimum replication configuration. If you choose to add optional replication configurations, you must grant additional permissions to Amazon S3:

- To replicate encrypted objects, you also need to grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called "Replicating encrypted objects"](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called "Using Object Lock with S3 Replication"](#).

Granting permissions when the source and destination buckets are owned by different AWS accounts

When the source and destination buckets aren't owned by the same accounts, the owner of the destination bucket must also add a bucket policy to grant the owner of the source bucket permissions to perform replication actions, as shown in the following example. In this example policy, `amzn-s3-demo-destination-bucket` is the destination bucket.

You can also use the Amazon S3 console to automatically generate this bucket policy for you. For more information, see [Enable receiving replicated objects from a source bucket](#).

Note

The ARN format of the role might appear different. If the role was created by using the console, the ARN format is `arn:aws:iam::account-ID:role/service-role/role-name`. If the role was created by using the AWS CLI, the ARN format is `arn:aws:iam::account-ID:role/role-name`. For more information, see [IAM roles](#) in the *IAM User Guide*.

```
"Version":"2012-10-17",
"Id":"PolicyForDestinationBucket",
"Statement": [
  {
    "Sid":"Permissions on objects",
    "Effect":"Allow",
    "Principal":{
      "AWS":"arn:aws:iam::source-bucket-account-ID:role/service-role/source-
account-IAM-role"
    },
    "Action":[
      "s3:ReplicateDelete",
      "s3:ReplicateObject"
    ],
    "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
  },
  {
    "Sid":"Permissions on bucket",
    "Effect":"Allow",
    "Principal":{
      "AWS":"arn:aws:iam::source-bucket-account-ID:role/service-role/source-
account-IAM-role"
    },
    "Action": [
      "s3>List*",
      "s3:GetBucketVersioning",
      "s3:PutBucketVersioning"
    ],
    "Resource":"arn:aws:s3:::amzn-s3-demo-destination-bucket"
  }
]
```

For an example, see [Configuring replication for buckets in different accounts](#).

If objects in the source bucket are tagged, note the following:

- If the source bucket owner grants Amazon S3 permission for the `s3:GetObjectVersionTagging` and `s3:ReplicateTags` actions to replicate object tags (through the IAM role), Amazon S3 replicates the tags along with the objects. For information about the IAM role, see [Creating an IAM role](#).

- If the owner of the destination bucket doesn't want to replicate the tags, they can add the following statement to the destination bucket policy to explicitly deny permission for the s3:ReplicateTags action. In this policy, `amzn-s3-demo-destination-bucket` is the destination bucket.

```
...
"Statement": [
  {
    "Effect": "Deny",
    "Principal": {
      "AWS": "arn:aws:iam::source-bucket-account-id:role/service-role/source-
account-IAM-role"
    },
    "Action": "s3:ReplicateTags",
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
  }
]
...
...
```

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

Enable receiving replicated objects from a source bucket

Instead of manually adding the preceding policy to your destination bucket, you can quickly generate the policies needed to enable receiving replicated objects from a source bucket through the Amazon S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the bucket that you want to use as a destination bucket.
4. Choose the **Management** tab, and scroll down to **Replication rules**.
5. For **Actions**, choose **Receive replicated objects**.

Follow the prompts and enter the AWS account ID of the source bucket account, and then choose **Generate policies**. The console generates an Amazon S3 bucket policy and a KMS key policy.

6. To add this policy to your existing bucket policy, either choose **Apply settings** or choose **Copy** to manually copy the changes.
7. (Optional) Copy the AWS KMS policy to your desired KMS key policy in the AWS Key Management Service console.

Changing replica ownership

When different AWS accounts own the source and destination buckets, you can tell Amazon S3 to change the ownership of the replica to the AWS account that owns the destination bucket. For more information about owner override, see [Changing the replica owner](#).

Granting permissions for S3 Batch Operations

S3 Batch Replication provides you a way to replicate the following objects:

- Objects that existed before a replication configuration was in place
- Objects that have previously been replicated
- Objects that have failed replication

You can create a one-time Batch Replication job when creating the first rule in a new replication configuration or when adding a new destination to an existing configuration through the Amazon S3 console. You can also initiate Batch Replication for an existing replication configuration by creating a Batch Operations job.

For a Batch Replication IAM role and policy examples, see [Configuring an IAM role for S3 Batch Replication](#).

Examples for configuring live replication

The following examples provide step-by-step walkthroughs that show how to configure live replication for common use cases.

Note

Live replication refers to Same-Region Replication (SRR) and Cross-Region Replication (CRR). Live replication doesn't replicate any objects that existed in the bucket before you set up replication. To replicate objects that existed before you set up replication, use on-demand replication. To sync buckets and replicate existing objects on demand, see [Replicating existing objects](#).

These examples demonstrate how to create a replication configuration by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDKs (AWS SDK for Java and AWS SDK for .NET examples are shown).

For information about installing and configuring the AWS CLI, see the following topics in the *AWS Command Line Interface User Guide*:

- [Get started with the AWS CLI](#)
- [Configure the AWS CLI](#) – You must set up at least one profile. If you are exploring cross-account scenarios, set up two profiles.

For information about the AWS SDKs, see [AWS SDK for Java](#) and [AWS SDK for .NET](#).

Tip

For a step-by-step tutorial that demonstrates how to use live replication to replicate data, see [Tutorial: Replicating data within and between AWS Regions using S3 Replication](#).

Topics

- [Configuring replication for buckets in different accounts](#)
- [Meeting compliance requirements with S3 Replication Time Control](#)

- [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#)
- [Replicating metadata changes with replica modification sync](#)
- [Replicating delete markers between buckets](#)

Configuring replication for buckets in the same account

Live replication is the automatic, asynchronous copying of objects across general purpose buckets in the same or different AWS Regions. Live replication copies newly created objects and object updates from a source bucket to a destination bucket or buckets. For more information, see [Replicating objects within and across Regions](#).

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

In this example, you set up live replication for source and destination buckets that are owned by the same AWS account. Examples are provided for using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDK for Java and AWS SDK for .NET.

Prerequisites

Before you use the following procedures, make sure that you've set up the necessary permissions for replication, depending on whether the source and destination buckets are owned by the same or different accounts. For more information, see [the section called "Setting up permissions"](#).

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

Using the S3 console

To configure a replication rule when the destination bucket is in the same AWS account as the source bucket, follow these steps.

If the destination bucket is in a different account from the source bucket, you must add a bucket policy to the destination bucket to grant the owner of the source bucket account permission to replicate objects in the destination bucket. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want.
4. Choose the **Management** tab, scroll down to **Replication rules**, and then choose **Create replication rule**.
5. In the **Replication rule configuration** section, under **Replication rule name**, enter a name for your rule to help identify the rule later. The name is required and must be unique within the bucket.
6. Under **Status**, **Enabled** is selected by default. An enabled rule starts to work as soon as you save it. If you want to enable the rule later, choose **Disabled**.

7. If the bucket has existing replication rules, you are instructed to set a priority for the rule. You must set a priority for the rule to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration file elements](#).
8. Under **Source bucket**, you have the following options for setting the replication source:
 - To replicate the whole bucket, choose **Apply to all objects in the bucket**.
 - To replicate all objects that have the same prefix, choose **Limit the scope of this rule using one or more filters**. This limits replication to all objects that have names that begin with the prefix that you specify (for example pictures). Enter a prefix in the **Prefix** box.

 **Note**

If you enter a prefix that is the name of a folder, you must use / (forward slash) as the last character (for example, pictures/).

- To replicate all objects with one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. Repeat the procedure to add another tag. You can combine a prefix and tags. For more information about object tags, see [Categorizing your storage using tags](#).

The new replication configuration XML schema supports prefix and tag filtering and the prioritization of rules. For more information about the new schema, see [Backward compatibility considerations](#). For more information about the XML used with the Amazon S3 API that works behind the user interface, see [Replication configuration file elements](#). The new schema is described as *replication configuration XML V2*.

9. Under **Destination**, choose the bucket where you want Amazon S3 to replicate objects.

 **Note**

The number of destination buckets is limited to the number of AWS Regions in a given partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud (US) Regions). To request an increase in your destination bucket quota, you can use [service quotas](#).

- To replicate to a bucket or buckets in your account, choose **Choose a bucket in this account**, and enter or browse for the destination bucket names.
- To replicate to a bucket or buckets in a different AWS account, choose **Specify a bucket in another account**, and enter the destination bucket account ID and bucket name.

If the destination is in a different account from the source bucket, you must add a bucket policy to the destination buckets to grant the owner of the source bucket account permission to replicate objects. For more information, see [Granting permissions when the source and destination buckets are owned by different AWS accounts](#).

Optionally, if you want to help standardize ownership of new objects in the destination bucket, choose **Change object ownership to the destination bucket owner**. For more information about this option, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

 **Note**

If versioning is not enabled on the destination bucket, you get a warning that contains an **Enable versioning** button. Choose this button to enable versioning on the bucket.

10. Set up an AWS Identity and Access Management (IAM) role that Amazon S3 can assume to replicate objects on your behalf.

To set up an IAM role, in the **IAM role** section, select one of the following from the **IAM role** dropdown list:

- We highly recommend that you choose **Create new role** to have Amazon S3 create a new IAM role for you. When you save the rule, a new policy is generated for the IAM role that matches the source and destination buckets that you choose.
- You can choose to use an existing IAM role. If you do, you must choose a role that grants Amazon S3 the necessary permissions for replication. Replication fails if this role does not grant Amazon S3 sufficient permissions to follow your replication rule.

⚠️ Important

When you add a replication rule to a bucket, you must have the `iam:PassRole` permission to be able to pass the IAM role that grants Amazon S3 replication permissions. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

11. To replicate objects in the source bucket that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), under **Encryption**, select **Replicate objects encrypted with AWS KMS**. Under **AWS KMS keys for encrypting destination objects** are the source keys that you allow replication to use. All source KMS keys are included by default. To narrow the KMS key selection, you can choose an alias or key ID.

Objects encrypted by AWS KMS keys that you do not select are not replicated. A KMS key or a group of KMS keys is chosen for you, but you can choose the KMS keys if you want. For information about using AWS KMS with replication, see [Replicating encrypted objects \(SSE-S3, SSE-KMS, DSSE-KMS, SSE-C\)](#).

⚠️ Important

When you replicate objects that are encrypted with AWS KMS, the AWS KMS request rate doubles in the source Region and increases in the destination Region by the same amount. These increased call rates to AWS KMS are due to the way that data is re-encrypted by using the KMS key that you define for the replication destination Region. AWS KMS has a request rate quota that is per calling account per Region. For information about the quota defaults, see [AWS KMS Quotas - Requests per Second: Varies in the AWS Key Management Service Developer Guide](#).

If your current Amazon S3 PUT object request rate during replication is more than half the default AWS KMS rate limit for your account, we recommend that you request an increase to your AWS KMS request rate quota. To request an increase, create a case in the Support Center at [Contact Us](#). For example, suppose that your current PUT object request rate is 1,000 requests per second and you use AWS KMS to encrypt your objects. In this case, we recommend that you ask Support to increase your AWS KMS rate limit to 2,500 requests per second, in both your source and destination Regions (if different), to ensure that there is no throttling by AWS KMS.

To see your PUT object request rate in the source bucket, view PutRequests in the Amazon CloudWatch request metrics for Amazon S3. For information about viewing CloudWatch metrics, see [Using the S3 console](#).

If you chose to replicate objects encrypted with AWS KMS, do the following:

- Under **AWS KMS key for encrypting destination objects**, specify your KMS key in one of the following ways:
 - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.
 - To enter the KMS key Amazon Resource Name (ARN), choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears. This encrypts the replicas in the destination bucket. You can find the ARN for your KMS key in the [IAM Console](#), under **Encryption keys**.
 - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

Important

You can only use KMS keys that are enabled in the same AWS Region as the bucket. When you choose **Choose from your KMS keys**, the S3 console lists only 100 KMS keys per Region. If you have more than 100 KMS keys in the same Region, you can see only the first 100 KMS keys in the S3 console. To use a KMS key that is not listed in the console, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN.

When you use an AWS KMS key for server-side encryption in Amazon S3, you must choose a symmetric encryption KMS key. Amazon S3 supports only symmetric encryption KMS keys and not asymmetric KMS keys. For more information, see

[Identifying symmetric and asymmetric KMS keys in the AWS Key Management Service Developer Guide.](#)

For more information about creating an AWS KMS key, see [Creating keys](#) in the *AWS Key Management Service Developer Guide*. For more information about using AWS KMS with Amazon S3, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

12. Under **Destination storage class**, if you want to replicate your data into a specific storage class in the destination, choose **Change the storage class for the replicated objects**. Then choose the storage class that you want to use for the replicated objects in the destination. If you don't choose this option, the storage class for replicated objects is the same class as the original objects.
13. You have the following additional options while setting the **Additional replication options**:
 - If you want to enable S3 Replication Time Control (S3 RTC) in your replication configuration, select **Replication Time Control (RTC)**. For more information about this option, see [Meeting compliance requirements with S3 Replication Time Control](#).
 - If you want to enable S3 Replication metrics in your replication configuration, select **Replication metrics and events**. For more information see, [Monitoring replication with metrics, event notifications, and statuses](#).
 - If you want to enable delete marker replication in your replication configuration, select **Delete marker replication**. For more information see, [Replicating delete markers between buckets](#).
 - If you want to enable Amazon S3 replica modification sync in your replication configuration, select **Replica modification sync**. For more information see, [Replicating metadata changes with replica modification sync](#).

 **Note**

When you use S3 RTC or S3 Replication metrics, additional fees apply.

14. To finish, choose **Save**.
15. After you save your rule, you can edit, enable, disable, or delete your rule by selecting your rule and choosing **Edit rule**.

Using the AWS CLI

To use the AWS CLI to set up replication when the source and destination buckets are owned by the same AWS account, you do the following:

- Create source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.
- Add the replication configuration to the source bucket.

To verify your setup, you test it.

To set up replication when the source and destination buckets are owned by the same AWS account

1. Set a credentials profile for the AWS CLI. This example uses the profile name acctA. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

Important

The profile that you use for this example must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. For more information, see [Grant a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*. If you use administrator credentials to create a named profile, you can perform all the tasks.

2. Create a source bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the `user input placeholders` with your own information.

The following `create-bucket` command creates a source bucket named `amzn-s3-demo-source-bucket` in the US East (N. Virginia) (us-east-1) Region:

```
aws s3api create-bucket \
```

```
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

The following put-bucket-versioning command enables S3 Versioning on the *amzn-s3-demo-source-bucket* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning on it by using the following AWS CLI commands. To use these commands, replace the *user input placeholders* with your own information.

 **Note**

To set up a replication configuration when both source and destination buckets are in the same AWS account, you use the same profile for the source and destination buckets. This example uses acctA.

To test a replication configuration when the buckets are owned by different AWS accounts, specify different profiles for each account. For example, use an acctB profile for the destination bucket.

The following create-bucket command creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (us-west-2) Region:

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctA
```

The following put-bucket-versioning command enables S3 Versioning on the *amzn-s3-demo-destination-bucket* bucket:

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

4. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a role.
- Attach a permissions policy to the role.

a. Create the IAM role.

- i. Copy the following trust policy and save it to a file named `s3-role-trust-policy.json` in the current directory on your local computer. This policy grants the Amazon S3 service principal permissions to assume the role.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Run the following command to create a role.

```
$ aws iam create-role \
--role-name replicationRole \
--assume-role-policy-document file://s3-role-trust-policy.json \
--profile acctA
```

b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named s3-role-permissions-policy.json in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetObjectVersionForReplication",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>ListBucket",  
                "s3:GetReplicationConfiguration"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ReplicateTags"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        }  
    ]  
}
```

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

- ii. Run the following command to create a policy and attach it to the role. Replace the *user input placeholders* with your own information.

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-permissions-policy.json \
--policy-name replicationRolePolicy \
--profile acctA
```

5. Add a replication configuration to the source bucket.

- a. Although the Amazon S3 API requires that you specify the replication configuration as XML, the AWS CLI requires that you specify the replication configuration as JSON. Save the following JSON in a file called `replication.json` to the local directory on your computer.

```
{
  "Role": "IAM-role-ARN",
  "Rules": [
    {
      "Status": "Enabled",
      "Priority": 1,
      "DeleteMarkerReplication": { "Status": "Disabled" },
      "Filter" : { "Prefix": "Tax" },
      "Destination": {
```

```
        "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"
    }
}
]
```

- b. Update the JSON by replacing the values for the *amzn-s3-demo-destination-bucket* and *IAM-role-ARN* with your own information. Save the changes.
- c. Run the following put-bucket-replication command to add the replication configuration to your source bucket. Be sure to provide the source bucket name:

```
$ aws s3api put-bucket-replication \
--replication-configuration file://replication.json \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

To retrieve the replication configuration, use the get-bucket-replication command:

```
$ aws s3api get-bucket-replication \
--bucket amzn-s3-demo-source-bucket \
--profile acctA
```

6. Test the setup in the Amazon S3 console, by doing the following steps:
 - a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. In the left navigation pane, choose **Buckets**. In the **General purpose buckets** list, choose the source bucket.
 - c. In the source bucket, create a folder named *Tax*.
 - d. Add sample objects to the *Tax* folder in the source bucket.

 **Note**

The amount of time that it takes for Amazon S3 to replicate an object depends on the size of the object. For information about how to see the status of replication, see [Getting replication status information](#).

In the destination bucket, verify the following:

- That Amazon S3 replicated the objects.
- That the objects are replicas. On the **Properties** tab for your objects, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**. Make sure that this value is set to **REPLICA**.
- That the replicas are owned by the source bucket account. You can verify the object ownership on the **Permissions** tab for your objects.

If the source and destination buckets are owned by different accounts, you can add an optional configuration to tell Amazon S3 to change the replica ownership to the destination account. For an example, see [How to change the replica owner](#).

Using the AWS SDKs

Use the following code examples to add a replication configuration to a bucket with the AWS SDK for Java and AWS SDK for .NET, respectively.

Note

- If you want to replicate encrypted objects, you also must grant the necessary AWS Key Management Service (AWS KMS) key permissions. For more information, see [the section called “Replicating encrypted objects”](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).

Java

The following example adds a replication configuration to a bucket and then retrieves and verifies the configuration. For instructions on creating and testing a working sample, see [Getting Started](#) in the *AWS SDK for Java Developer Guide*.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;

import java.io.IOException;
import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

public class CrossRegionReplication {

    public static void main(String[] args) throws IOException {
        Regions clientRegion = Regions.DEFAULT_REGION;
        String accountId = "*** Account ID ***";
        String roleName = "*** Role name ***";
        String sourceBucketName = "*** Source bucket name ***";
        String destBucketName = "*** Destination bucket name ***";
        String prefix = "Tax/";
```

```
String roleARN = String.format("arn:aws:iam::%s:%s", accountId,
roleName);
String destinationBucketARN = "arn:aws:s3:::" + destBucketName;

AmazonS3 s3Client = AmazonS3Client.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(clientRegion)
    .build();

createBucket(s3Client, clientRegion, sourceBucketName);
createBucket(s3Client, clientRegion, destBucketName);
assignRole(roleName, clientRegion, sourceBucketName,
destBucketName);

try {

    // Create the replication rule.
    List<ReplicationFilterPredicate> andOperands = new
ArrayList<ReplicationFilterPredicate>();
    andOperands.add(new ReplicationPrefixPredicate(prefix));

    Map<String, ReplicationRule> replicationRules = new
HashMap<String, ReplicationRule>();
    replicationRules.put("ReplicationRule1",
        new ReplicationRule()
            .withPriority(0)

    .withStatus(ReplicationRuleStatus.Enabled)

    .withDeleteMarkerReplication(
        new
DeleteMarkerReplication().withStatus(
            DeleteMarkerReplicationStatus.DISABLED))
        .withFilter(new
ReplicationFilter().withPredicate(
            new
ReplicationPrefixPredicate(prefix)))
        .withDestinationConfig(new
ReplicationDestinationConfig()

    .withBucketARN(destinationBucketARN)

    .withStorageClass(StorageClass.Standard)));
}
```

```
// Save the replication rule to the source bucket.  
s3Client.setBucketReplicationConfiguration(sourceBucketName,  
                                             new BucketReplicationConfiguration()  
                                               .withRoleARN(roleARN)  
  
.withRules(replicationRules));  
  
        // Retrieve the replication configuration and verify that  
the configuration  
        // matches the rule we just set.  
        BucketReplicationConfiguration replicationConfig = s3Client  
  
.getBucketReplicationConfiguration(sourceBucketName);  
        ReplicationRule rule =  
replicationConfig.getRule("ReplicationRule1");  
        System.out.println("Retrieved destination bucket ARN: "  
                           +  
rule.getDestinationConfig().getBucketARN());  
        System.out.println("Retrieved priority: " +  
rule.getPriority());  
        System.out.println("Retrieved source-bucket replication rule  
status: " + rule.getStatus());  
    } catch (AmazonServiceException e) {

      .withPolicyDocument(permissionPolicy.toString())
      .withPolicyName("crrRolePolicy");

      iamClient.putRolePolicy(putRolePolicyRequest);

    }
}
```

C#

The following AWS SDK for .NET code example adds a replication configuration to a bucket and then retrieves it. To use this code, provide the names for your buckets and the Amazon Resource Name (ARN) for your IAM role. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CrossRegionReplicationTest
    {
        private const string sourceBucket = "*** source bucket ***";
        // Bucket ARN example - arn:aws:s3:::destinationbucket
        private const string destinationBucketArn = "*** destination bucket ARN ***";
        private const string roleArn = "*** IAM Role ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint sourceBucketRegion =

}  
}  
}  
}
```

Configuring replication for buckets in different accounts

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. Live replication copies newly created objects and object updates from a source bucket to a destination bucket or buckets. For more information, see [Replicating objects within and across Regions](#).

When you configure replication, you add replication rules to the source bucket. Replication rules define which source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. You can create a rule to replicate all the objects in a bucket or a subset of objects with a specific key name prefix, one or more object tags, or both. A destination bucket can be in the same AWS account as the source bucket, or it can be in a different account.

If you specify an object version ID to delete, Amazon S3 deletes that object version in the source bucket. But it doesn't replicate the deletion in the destination bucket. In other words, it doesn't delete the same object version from the destination bucket. This protects data from malicious deletions.

When you add a replication rule to a bucket, the rule is enabled by default, so it starts working as soon as you save it.

Setting up live replication when the source and destination buckets are owned by different AWS accounts is similar to setting up replication when both buckets are owned by the same account. However, there are several differences when you're configuring replication in a cross-account scenario:

- The destination bucket owner must grant the source bucket owner permission to replicate objects in the destination bucket policy.
- If you're replicating objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) in a cross-account scenario, the owner of the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see [Granting additional permissions for cross-account scenarios](#).
- By default, replicated objects are owned by the source bucket owner. In a cross-account scenario, you might want to configure replication to change the ownership of the replicated objects to the owner of the destination bucket. For more information, see [Changing the replica owner](#).

To configure replication when the source and destination buckets are owned by different AWS accounts

1. In this example, you create source and destination buckets in two different AWS accounts. You must have two credential profiles set for the AWS CLI. This example uses acctA and acctB for those profile names. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.
2. Follow the step-by-step instructions in [Configuring replication for buckets in the same account](#) with the following changes:
 - For all AWS CLI commands related to source bucket activities (such as creating the source bucket, enabling versioning, and creating the IAM role), use the acctA profile. Use the acctB profile to create the destination bucket.
 - Make sure that the permissions policy for the IAM role specifies the source and destination buckets that you created for this example.
3. In the console, add the following bucket policy on the destination bucket to allow the owner of the source bucket to replicate objects. For instructions, see [Adding a bucket policy by using the Amazon S3 console](#). Be sure to edit the policy by providing the AWS account ID of the source bucket owner, the IAM role name, and the destination bucket name.

Note

To use the following example, replace the *user input placeholders* with your own information. Replace *amzn-s3-demo-destination-bucket* with your destination bucket name. Replace *source-bucket-account-ID:role/service-*

role/source-account-IAM-role in the IAM Amazon Resource Name (ARN) with the IAM role that you're using for this replication configuration. If you created the IAM service role manually, set the role path in the IAM ARN as `role/service-role/`, as shown in the following policy example. For more information, see [IAM ARNs](#) in the *IAM User Guide*.

```
{  
    "Version": "2012-10-17",  
    "Id": "",  
    "Statement": [  
        {  
            "Sid": "Set-permissions-for-objects",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::source-bucket-account-ID:role/service-role/source-  
account-IAM-role"  
            },  
            "Action": ["s3:ReplicateObject", "s3:ReplicateDelete"],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        },  
        {  
            "Sid": "Set permissions on bucket",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::source-bucket-account-ID:role/service-role/source-  
account-IAM-role"  
            },  
            "Action": ["s3:GetBucketVersioning", "s3:PutBucketVersioning"],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket"  
        }  
    ]  
}
```

4. (Optional) If you're replicating objects that are encrypted with SSE-KMS, the owner of the KMS key must grant the source bucket owner permission to use the KMS key. For more information, see [Granting additional permissions for cross-account scenarios](#).
5. (Optional) In replication, the owner of the source object owns the replica by default. When the source and destination buckets are owned by different AWS accounts, you can add optional configuration settings to change replica ownership to the AWS account that owns

the destination buckets. This includes granting the `ObjectOwnerOverrideToBucketOwner` permission. For more information, see [Changing the replica owner](#).

Changing the replica owner

In replication, the owner of the source object also owns the replica by default. However, when the source and destination buckets are owned by different AWS accounts, you might want to change the replica ownership. For example, you might want to change the ownership to restrict access to object replicas. In your replication configuration, you can add optional configuration settings to change replica ownership to the AWS account that owns the destination buckets.

To change the replica owner, you do the following:

- Add the `owner override` option to the replication configuration to tell Amazon S3 to change replica ownership.
- Grant Amazon S3 the `s3:ObjectOwnerOverrideToBucketOwner` permission to change replica ownership.
- Add the `s3:ObjectOwnerOverrideToBucketOwner` permission in the destination bucket policy to allow changing replica ownership. The `s3:ObjectOwnerOverrideToBucketOwner` permission allows the owner of the destination buckets to accept the ownership of object replicas.

For more information, see [the section called “Considerations for the ownership override option”](#) and [Adding the owner override option to the replication configuration](#). For a working example with step-by-step instructions, see [How to change the replica owner](#).

Important

Instead of using the owner override option, you can use the bucket owner enforced setting for Object Ownership. When you use replication and the source and destination buckets are owned by different AWS accounts, the bucket owner of the destination bucket can use the bucket owner enforced setting for Object Ownership to change replica ownership to the AWS account that owns the destination bucket. This setting disables object access control lists (ACLs).

The bucket owner enforced setting mimics the existing owner override behavior without the need of the `s3:ObjectOwnerOverrideToBucketOwner` permission. All objects that are replicated to the destination bucket with the bucket owner enforced setting are

owned by the destination bucket owner. For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Considerations for the ownership override option

When you configure the ownership override option, the following considerations apply:

- By default, the owner of the source object also owns the replica. Amazon S3 replicates the object version and the ACL associated with it.

If you add the owner override option to your replication configuration, Amazon S3 replicates only the object version, not the ACL. In addition, Amazon S3 doesn't replicate subsequent changes to the source object ACL. Amazon S3 sets the ACL on the replica that grants full control to the destination bucket owner.

- When you update a replication configuration to enable or disable the owner override, the following behavior occurs:
 - If you add the owner override option to the replication configuration:

When Amazon S3 replicates an object version, it discards the ACL that's associated with the source object. Instead, Amazon S3 sets the ACL on the replica, giving full control to the owner of the destination bucket. Amazon S3 doesn't replicate subsequent changes to the source object ACL. However, this ACL change doesn't apply to object versions that were replicated before you set the owner override option. ACL updates on source objects that were replicated before the owner override was set continue to be replicated (because the object and its replicas continue to have the same owner).

- If you remove the owner override option from the replication configuration:

Amazon S3 replicates new objects that appear in the source bucket and the associated ACLs to the destination buckets. For objects that were replicated before you removed the owner override, Amazon S3 doesn't replicate the ACLs because the object ownership change that Amazon S3 made remains in effect. That is, ACLs put on the object version that were replicated when the owner override was set continue to be not replicated.

Adding the owner override option to the replication configuration

Warning

Add the owner override option only when the source and destination buckets are owned by different AWS accounts. Amazon S3 doesn't check if the buckets are owned by the same or different accounts. If you add the owner override when both buckets are owned by same AWS account, Amazon S3 applies the owner override. This option grants full permissions to the owner of the destination bucket and doesn't replicate subsequent updates to the source objects' access control lists (ACLs). The replica owner can directly change the ACL associated with a replica with a PutObjectAcl request, but not through replication.

To specify the owner override option, add the following to each Destination element:

- The AccessControlTranslation element, which tells Amazon S3 to change replica ownership
- The Account element, which specifies the AWS account of the destination bucket owner

```
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    ...
    <Destination>
        ...
        <AccessControlTranslation>
            <Owner>Destination</Owner>
        </AccessControlTranslation>
        <Account>destination-bucket-owner-account-id</Account>
    </Destination>
</Rule>
</ReplicationConfiguration>
```

The following example replication configuration tells Amazon S3 to replicate objects that have the **Tax** key prefix to the **amzn-s3-demo-destination-bucket** destination bucket and change ownership of the replicas. To use this example, replace the **user input placeholders** with your own information.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
```

```
<Role>arn:aws:iam::account-id:role/role-name</Role>
<Rule>
  <ID>Rule-1</ID>
  <Priority>1</Priority>
  <Status>Enabled</Status>
  <DeleteMarkerReplication>
    <Status>Disabled</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>Tax</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    <Account>destination-bucket-owner-account-id</Account>
    <AccessControlTranslation>
      <Owner>Destination</Owner>
    </AccessControlTranslation>
  </Destination>
</Rule>
</ReplicationConfiguration>
```

Granting Amazon S3 permission to change replica ownership

Grant Amazon S3 permissions to change replica ownership by adding permission for the `s3:ObjectOwnerOverrideToBucketOwner` action in the permissions policy that's associated with the AWS Identity and Access Management (IAM) role. This role is the IAM role that you specified in the replication configuration that allows Amazon S3 to assume and replicate objects on your behalf. To use the following example, replace `amzn-s3-demo-destination-bucket` with the name of the destination bucket.

```
...
{
  "Effect": "Allow",
  "Action": [
    "s3:ObjectOwnerOverrideToBucketOwner"
  ],
  "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
...
```

Adding permission in the destination bucket policy to allow changing replica ownership

The owner of the destination bucket must grant the owner of the source bucket permission to change replica ownership. The owner of the destination bucket grants the owner of the source bucket permission for the `s3:ObjectOwnerOverrideToBucketOwner` action. This permission allows the destination bucket owner to accept ownership of the object replicas. The following example bucket policy statement shows how to do this. To use this example, replace the *user input placeholders* with your own information.

```
...
{
    "Sid": "1",
    "Effect": "Allow",
    "Principal": {"AWS": "source-bucket-account-id"},
    "Action": ["s3:ObjectOwnerOverrideToBucketOwner"],
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
...
```

How to change the replica owner

When the source and destination buckets in a replication configuration are owned by different AWS accounts, you can tell Amazon S3 to change replica ownership to the AWS account that owns the destination bucket. The following examples show how to use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), and the AWS SDKs to change replica ownership.

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#).

This topic provides instructions for setting up a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

The following procedure shows how to change replica ownership by using the AWS CLI. In this procedure, you do the following:

- Create the source and destination buckets.
- Enable versioning on the buckets.
- Create an AWS Identity and Access Management (IAM) role that gives Amazon S3 permission to replicate objects.

- Add the replication configuration to the source bucket.
- In the replication configuration, you direct Amazon S3 to change the replica ownership.
- You test your replication configuration.

To change replica ownership when the source and destination buckets are owned by different AWS accounts (AWS CLI)

To use the example AWS CLI commands in this procedure, replace the *user input placeholders* with your own information.

1. In this example, you create the source and destination buckets in two different AWS accounts. To work with these two accounts, configure the AWS CLI with two named profiles. This example uses profiles named *acctA* and *acctB*, respectively. For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

Important

The profiles that you use for this procedure must have the necessary permissions. For example, in the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if the profile that you use has the `iam:PassRole` permission. If you use administrator user credentials to create a named profile, then you can perform all of the tasks in this procedure. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

2. Create the source bucket and enable versioning. This example creates a source bucket named *amzn-s3-demo-source-bucket* in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Create a destination bucket and enable versioning. This example creates a destination bucket named *amzn-s3-demo-destination-bucket* in the US West (Oregon) (us-west-2) Region. Use an AWS account profile that's different from the one that you used for the source bucket.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctB
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctB
```

4. You must add permissions to your destination bucket policy to allow changing the replica ownership.
- a. Save the following policy to a file named *destination-bucket-policy.json*. Make sure to replace the *user input placeholders* with your own information.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "destination_bucket_policy_sid",
            "Principal": {
                "AWS": "source-bucket-owner-account-id"
            },
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete",
                "s3:ObjectOwnerOverrideToBucketOwner",
                "s3:ReplicateTags",
                "s3:GetObjectVersionTagging"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
            ]
        }
    ]
}
```

```
        }
    ]
}
```

- b. Add the preceding policy to the destination bucket by using the following put-bucket-policy command:

```
aws s3api put-bucket-policy --region $ {destination-region} --bucket $ {amzn-s3-demo-destination-bucket} --policy file://destination_bucket_policy.json
```

5. Create an IAM role. You specify this role in the replication configuration that you add to the source bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create the role.
- Attach a permissions policy to the role.

- a. Create the IAM role.

- i. Copy the following trust policy and save it to a file named *s3-role-trust-policy.json* in the current directory on your local computer. This policy grants Amazon S3 permissions to assume the role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

- ii. Run the following AWS CLI create-role command to create the IAM role:

```
$ aws iam create-role \
--role-name replicationRole \
```

```
--assume-role-policy-document file://s3-role-trust-policy.json \
--profile acctA
```

Make note of the Amazon Resource Name (ARN) of the IAM role that you created. You will need this ARN in a later step.

b. Attach a permissions policy to the role.

- i. Copy the following permissions policy and save it to a file named *s3-role-perm-pol-changeowner*.json in the current directory on your local computer. This policy grants permissions for various Amazon S3 bucket and object actions. In the following steps, you attach this policy to the IAM role that you created earlier.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectVersionForReplication",
                "s3:GetObjectVersionAcl"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>ListBucket",
                "s3:GetReplicationConfiguration"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete",
                "s3:ObjectOwnerOverrideToBucketOwner",
                "s3:ReplicateTags",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        }
    ]
}
```

```
        "s3:GetObjectVersionTagging"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
}
]
}
```

- ii. To attach the preceding permissions policy to the role, run the following `put-role-policy` command:

```
$ aws iam put-role-policy \
--role-name replicationRole \
--policy-document file://s3-role-perm-pol-changeowner.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

6. Add a replication configuration to your source bucket.

- a. The AWS CLI requires specifying the replication configuration as JSON. Save the following JSON in a file named `replication.json` in the current directory on your local computer. In the configuration, the `AccessControlTranslation` specifies the change in replica ownership from the source bucket owner to the destination bucket owner.

```
{
    "Role": "IAM-role-ARN",
    "Rules": [
        {
            "Status": "Enabled",
            "Priority": 1,
            "DeleteMarkerReplication": {
                "Status": "Disabled"
            },
            "Filter": {},
            "Status": "Enabled",
            "Destination": {
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",
                "Account": "destination-bucket-owner-account-id",
                "AccessControlTranslation": {
                    "Owner": "Destination"
                }
            }
        }
    ]
}
```

```
    ]  
}
```

- b. Edit the JSON by providing values for the destination bucket name, the destination bucket owner account ID, and the *IAM-role-ARN*. Replace *IAM-role-ARN* with the ARN of the IAM role that you created earlier. Save the changes.
- c. To add the replication configuration to the source bucket, run the following command:

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket amzn-s3-demo-source-bucket \  
--profile acctA
```

7. Test your replication configuration by checking replica ownership in the Amazon S3 console.
 - a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. Add objects to the source bucket. Verify that the destination bucket contains the object replicas and that the ownership of the replicas has changed to the AWS account that owns the destination bucket.

Using the AWS SDKs

For a code example to add a replication configuration, see [Using the AWS SDKs](#). You must modify the replication configuration appropriately. For conceptual information, see [Changing the replica owner](#).

Meeting compliance requirements with S3 Replication Time Control

S3 Replication Time Control (S3 RTC) helps you meet compliance or business requirements for data replication and provides visibility into Amazon S3 replication times. S3 RTC replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes.

By default, S3 RTC includes two ways to track the progress of replication:

- **S3 Replication metrics** – You can use S3 Replication metrics to monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination Region, and the total number of operations that failed replication. You can then monitor each dataset that you replicate separately. You can also

enable S3 Replication metrics independently of S3 RTC. For more information, see [the section called “Using S3 Replication metrics”](#).

Replication rules with S3 Replication Time Control (S3 RTC) enabled publish S3 Replication metrics. Replication metrics are available within 15 minutes of enabling S3 RTC. Replication metrics are available through the Amazon S3 console, the Amazon S3 API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), and Amazon CloudWatch. For more information about CloudWatch metrics, see [Monitoring metrics with Amazon CloudWatch](#). For more information about viewing replication metrics through the Amazon S3 console, see [Viewing replication metrics](#).

S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For information, see [Amazon CloudWatch pricing](#).

- **Amazon S3 Event Notifications** – S3 RTC provides OperationMissedThreshold and OperationReplicatedAfterThreshold events that notify the bucket owner if object replication exceeds or occurs after the 15-minute threshold. With S3 RTC, Amazon S3 Event Notifications can notify you in the rare instance when objects don't replicate within 15 minutes and when those objects replicate after the 15-minute threshold.

Replication events are available within 15 minutes of enabling S3 RTC. Amazon S3 Event Notifications are available through Amazon SQS, Amazon SNS, or AWS Lambda. For more information, see [the section called “Receiving replication failure events”](#).

Best practices and guidelines for S3 RTC

When replicating data in Amazon S3 with S3 Replication Time Control (S3 RTC) enabled, follow these best practice guidelines to optimize replication performance for your workloads.

Topics

- [Amazon S3 Replication and request rate performance guidelines](#)
- [Estimating your replication request rates](#)
- [Exceeding S3 RTC data transfer rate quotas](#)
- [AWS KMS encrypted object replication request rates](#)

Amazon S3 Replication and request rate performance guidelines

When uploading and retrieving storage from Amazon S3, your applications can achieve thousands of transactions per second in request performance. For example, an application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix in an S3 bucket, including the requests that S3 Replication makes on your behalf. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by parallelizing reads. For example, if you create 10 prefixes in an S3 bucket to parallelize reads, you can scale your read performance to 55,000 read requests per second.

Amazon S3 automatically scales in response to sustained request rates above these guidelines, or sustained request rates concurrent with LIST requests. While Amazon S3 is internally optimizing for the new request rate, you might receive HTTP 503 request responses temporarily until the optimization is complete. This behavior might occur with increases in request per second rates, or when you first enable S3 RTC. During these periods, your replication latency might increase. The S3 RTC service level agreement (SLA) doesn't apply to time periods when Amazon S3 performance guidelines on requests per second are exceeded.

The S3 RTC SLA also doesn't apply during time periods where your replication data transfer rate exceeds the default 1 gigabit per second (Gbps) quota. If you expect your replication transfer rate to exceed 1 Gbps, you can contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your replication transfer rate quota.

Estimating your replication request rates

Your total request rate including the requests that Amazon S3 replication makes on your behalf must be within the Amazon S3 request rate guidelines for both the replication source and destination buckets. For each object replicated, Amazon S3 replication makes up to five GET/HEAD requests and one PUT request to the source bucket, and one PUT request to each destination bucket.

For example, if you expect to replicate 100 objects per second, Amazon S3 replication might perform an additional 100 PUT requests on your behalf for a total of 200 PUT requests per second to the source S3 bucket. Amazon S3 replication also might perform up to 500 GET/HEAD requests (5 GET/HEAD requests for each object that's replicated.)

Note

You incur costs for only one PUT request per object replicated. For more information, see the pricing information in the [Amazon S3 FAQs about replication](#).

Exceeding S3 RTC data transfer rate quotas

If you expect your S3 RTC data transfer rate to exceed the default 1 Gbps quota, contact [AWS Support Center](#) or use [Service Quotas](#) to request an increase in your replication transfer rate quota.

AWS KMS encrypted object replication request rates

When you replicate objects that are encrypted with server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), AWS KMS requests per second quotas apply. AWS KMS might reject an otherwise valid request because your request rate exceeds the quota for the number of requests per second. When a request is throttled, AWS KMS returns a ThrottlingException error. The AWS KMS request rate quota applies to requests that you make directly and to requests made by Amazon S3 replication on your behalf.

For example, if you expect to replicate 1,000 objects per second, you can subtract 2,000 requests from your AWS KMS request rate quota. The resulting request rate per second is available for your AWS KMS workloads excluding replication. You can use [AWS KMS request metrics in Amazon CloudWatch](#) to monitor the total AWS KMS request rate on your AWS account.

To request an increase to your AWS KMS requests per second quota, contact [AWS Support Center](#) or use [Service Quotas](#).

Enabling S3 Replication Time Control

You can start using S3 Replication Time Control (S3 RTC) with a new or existing replication rule. You can choose to apply your replication rule to an entire bucket, or to objects with a specific prefix or tag. When you enable S3 RTC, S3 Replication metrics are also enabled on your replication rule.

You can configure S3 RTC by using the Amazon S3 console, the Amazon S3 API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI).

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#). This topic provides instructions for enabling S3 RTC in your replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To use the AWS CLI to replicate objects with S3 RTC enabled, you create buckets, enable versioning on the buckets, create an IAM role that gives Amazon S3 permission to replicate objects, and add the replication configuration to the source bucket. The replication configuration must have S3 RTC enabled, as shown in the following example.

For step-by-step instructions for setting up your replication configuration by using the AWS CLI, see [Configuring replication for buckets in the same account](#).

The following example replication configuration enables and sets the `ReplicationTime` and `EventThreshold` values for a replication rule. Enabling and setting these values enables S3 RTC on the rule.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
                "Metrics": {  
                    "Status": "Enabled",  
                    "EventThreshold": {  
                        "Minutes": 15  
                    }  
                },  
                "ReplicationTime": {  
                    "Status": "Enabled",  
                    "Time": {  
                        "Minutes": 15  
                    }  
                }  
            }  
        }  
    ]  
}
```

```
        }
    },
    "Priority": 1
}
],
"Role": "IAM-Role-ARN"
}
```

Important

Metrics:EventThreshold:Minutes and ReplicationTime:Time:Minutes can only have 15 as a valid value.

Using the AWS SDK for Java

The following Java example adds replication configuration with S3 Replication Time Control (S3 RTC) enabled.

```
import software.amazon.awssdk.auth.credentials.AwsBasicCredentials;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.model.DeleteMarkerReplication;
import software.amazon.awssdk.services.s3.model.Destination;
import software.amazon.awssdk.services.s3.model.Metrics;
import software.amazon.awssdk.services.s3.model.MetricsStatus;
import software.amazon.awssdk.services.s3.model.PutBucketReplicationRequest;
import software.amazon.awssdk.services.s3.model.ReplicationConfiguration;
import software.amazon.awssdk.services.s3.model.ReplicationRule;
import software.amazon.awssdk.services.s3.model.ReplicationRuleFilter;
import software.amazon.awssdk.services.s3.model.ReplicationTime;
import software.amazon.awssdk.services.s3.model.ReplicationTimeStatus;
import software.amazon.awssdk.services.s3.model.ReplicationTimeValue;

public class Main {

    public static void main(String[] args) {
        S3Client s3 = S3Client.builder()
            .region(Region.US_EAST_1)
            .credentialsProvider(() -> AwsBasicCredentials.create(
                "AWS_ACCESS_KEY_ID",
                "AWS_SECRET_ACCESS_KEY")
        )
    }
}
```

```
.build();

ReplicationConfiguration replicationConfig = ReplicationConfiguration
    .builder()
    .rules(
        ReplicationRule
            .builder()
            .status("Enabled")
            .priority(1)
            .deleteMarkerReplication(
                DeleteMarkerReplication
                    .builder()
                    .status("Disabled")
                    .build()
            )
    )
    .destination(
        Destination
            .builder()
            .bucket("destination_bucket_arn")
            .replicationTime(
                ReplicationTime.builder().time(
                    ReplicationTimeValue.builder().minutes(15).build()
                ).status(
                    ReplicationTimeStatus.ENABLED
                ).build()
            )
            .metrics(
                Metrics.builder().eventThreshold(
                    ReplicationTimeValue.builder().minutes(15).build()
                ).status(
                    MetricsStatus.ENABLED
                ).build()
            )
            .build()
    )
    .filter(
        ReplicationRuleFilter
            .builder()
            .prefix("testtest")
            .build()
    )
    .build())
    .role("role_arn")
    .build();
```

```
// Put replication configuration
PutBucketReplicationRequest putBucketReplicationRequest =
PutBucketReplicationRequest
    .builder()
    .bucket("source_bucket")
    .replicationConfiguration(replicationConfig)
    .build();

s3.putBucketReplication(putBucketReplicationRequest);
}

}
```

Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C)

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

There are some special considerations when you're replicating objects that have been encrypted by using server-side encryption. Amazon S3 supports the following types of server-side encryption:

- Server-side encryption with Amazon S3 managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)
- Dual-layer server-side encryption with AWS KMS keys (DSSE-KMS)
- Server-side encryption with customer-provided keys (SSE-C)

For more information about server-side encryption, see [the section called “Server-side encryption”](#).

This topic explains the permissions that you need to direct Amazon S3 to replicate objects that have been encrypted by using server-side encryption. This topic also provides additional configuration elements that you can add and example AWS Identity and Access Management (IAM) policies that grant the necessary permissions for replicating encrypted objects.

For an example with step-by-step instructions, see [Enabling replication for encrypted objects](#). For information about creating a replication configuration, see [Replicating objects within and across Regions](#).

 **Note**

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Topics

- [How default bucket encryption affects replication](#)
- [Replicating objects encrypted with SSE-C](#)
- [Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS](#)
- [Enabling replication for encrypted objects](#)

How default bucket encryption affects replication

When you enable default encryption for a replication destination bucket, the following encryption behavior applies:

- If objects in the source bucket are not encrypted, the replica objects in the destination bucket are encrypted by using the default encryption settings of the destination bucket. As a result, the entity tags (ETags) of the source objects differ from the ETags of the replica objects. If you have applications that use ETags, you must update those applications to account for this difference.
- If objects in the source bucket are encrypted by using server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), the replica objects in the destination bucket use the same type of encryption as the source objects. The default encryption settings of the destination bucket are not used.

Replicating objects encrypted with SSE-C

By using server-side encryption with customer-provided keys (SSE-C), you can manage your own proprietary encryption keys. With SSE-C, you manage the keys while Amazon S3 manages the encryption and decryption process. You must provide an encryption key as part of your request, but you don't need to write any code to perform object encryption or decryption. When you upload an object, Amazon S3 encrypts the object by using the key that you provided. Amazon S3 then purges that key from memory. When you retrieve an object, you must provide the same encryption key as part of your request. For more information, see [the section called "Customer-provided encryption keys \(SSE-C\)"](#).

S3 Replication supports objects that are encrypted with SSE-C. You can configure SSE-C object replication in the Amazon S3 console or with the AWS SDKs in the same way that you configure replication for unencrypted objects. There aren't additional SSE-C permissions beyond what are currently required for replication.

S3 Replication automatically replicates newly uploaded SSE-C encrypted objects if they are eligible, as specified in your S3 Replication configuration. To replicate existing objects in your buckets, use S3 Batch Replication. For more information about replicating objects, see [the section called "Setting up live replication"](#) and [the section called "Replicating existing objects"](#).

There are no additional charges for replicating SSE-C objects. For details about replication pricing, see [Amazon S3 pricing](#).

Replicating objects encrypted with SSE-S3, SSE-KMS, or DSSE-KMS

By default, Amazon S3 doesn't replicate objects that are encrypted with SSE-KMS or DSSE-KMS. This section explains the additional configuration elements that you can add to direct Amazon S3 to replicate these objects.

For an example with step-by-step instructions, see [Enabling replication for encrypted objects](#). For information about creating a replication configuration, see [Replicating objects within and across Regions](#).

Specifying additional information in the replication configuration

In the replication configuration, you do the following:

- In the Destination element in your replication configuration, add the ID of the symmetric AWS KMS customer managed key that you want Amazon S3 to use to encrypt object replicas, as shown in the following example replication configuration.

- Explicitly opt in by enabling replication of objects encrypted by using KMS keys (SSE-KMS or DSSE-KMS). To opt in, add the `SourceSelectionCriteria` element, as shown in the following example replication configuration.

```
<ReplicationConfiguration>
  <Rule>
    ...
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>

    <Destination>
      ...
      <EncryptionConfiguration>
        <ReplicaKmsKeyID>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket.</ReplicaKmsKeyID>
      </EncryptionConfiguration>
    </Destination>
    ...
  </Rule>
</ReplicationConfiguration>
```

Important

- The KMS key must have been created in the same AWS Region as the destination bucket.
- The KMS key *must* be valid. The `PutBucketReplication` API operation doesn't check the validity of KMS keys. If you use a KMS key that isn't valid, you will receive the `HTTP 200 OK` status code in response, but replication fails.

The following example shows a replication configuration that includes optional configuration elements. This replication configuration has one rule. The rule applies to objects with the `Tax` key prefix. Amazon S3 uses the specified AWS KMS key ID to encrypt these object replicas.

```
<?xml version="1.0" encoding="UTF-8"?>
<ReplicationConfiguration>
```

```
<Role>arn:aws:iam::account-id:role/role-name</Role>
<Rule>
  <ID>Rule-1</ID>
  <Priority>1</Priority>
  <Status>Enabled</Status>
  <DeleteMarkerReplication>
    <Status>Disabled</Status>
  </DeleteMarkerReplication>
  <Filter>
    <Prefix>Tax</Prefix>
  </Filter>
  <Destination>
    <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
    <EncryptionConfiguration>
      <ReplicaKmsKeyId>AWS KMS key ARN or Key Alias ARN that's in the same AWS Region as the destination bucket.</ReplicaKmsKeyId>
    </EncryptionConfiguration>
  </Destination>
  <SourceSelectionCriteria>
    <SseKmsEncryptedObjects>
      <Status>Enabled</Status>
    </SseKmsEncryptedObjects>
  </SourceSelectionCriteria>
  </Rule>
</ReplicationConfiguration>
```

Granting additional permissions for the IAM role

To replicate objects that are encrypted at rest by using SSE-S3, SSE-KMS, or DSSE-KMS, grant the following additional permissions to the AWS Identity and Access Management (IAM) role that you specify in the replication configuration. You grant these permissions by updating the permissions policy that's associated with the IAM role.

- **s3:GetObjectVersionForReplication action for source objects** – This action allows Amazon S3 to replicate both unencrypted objects and objects created with server-side encryption by using SSE-S3, SSE-KMS, or DSSE-KMS.

Note

We recommend that you use the s3:GetObjectVersionForReplication action instead of the s3:GetObjectVersion action because s3:GetObjectVersionForReplication provides Amazon S3 with only the minimum

permissions necessary for replication. In addition, the `s3:GetObjectVersion` action allows replication of unencrypted and SSE-S3-encrypted objects, but not of objects that are encrypted by using KMS keys (SSE-KMS or DSSE-KMS).

- **kms:Decrypt and kms:Encrypt AWS KMS actions for the KMS keys**

- You must grant `kms:Decrypt` permissions for the AWS KMS key that's used to decrypt the source object.
- You must grant `kms:Encrypt` permissions for the AWS KMS key that's used to encrypt the object replica.
- **kms:GenerateDataKey action for replicating plaintext objects** – If you're replicating plaintext objects to a bucket with SSE-KMS or DSSE-KMS encryption enabled by default, you must include the `kms:GenerateDataKey` permission for the destination encryption context and the KMS key in the IAM policy.

We recommend that you restrict these permissions only to the destination buckets and objects by using AWS KMS condition keys. The AWS account that owns the IAM role must have permissions for the `kms:Encrypt` and `kms:Decrypt` actions for the KMS keys that are listed in the policy. If the KMS keys are owned by another AWS account, the owner of the KMS keys must grant these permissions to the AWS account that owns the IAM role. For more information about managing access to these KMS keys, see [Using IAM policies with AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

S3 Bucket Keys and replication

To use replication with an S3 Bucket Key, the AWS KMS key policy for the KMS key that's used to encrypt the object replica must include the `kms:Decrypt` permission for the calling principal. The call to `kms:Decrypt` verifies the integrity of the S3 Bucket Key before using it. For more information, see [Using an S3 Bucket Key with replication](#).

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN (for example, `arn:aws:s3:::bucket_ARN`). You must update your IAM policies to use the bucket ARN for the encryption context:

```
"kms:EncryptionContext:aws:s3:arn": [
    "arn:aws:s3:::bucket_ARN"
]
```

For more information, see [Encryption context \(x-amz-server-side-encryption-context\)](#) (in the "Using the REST API" section) and [Changes to note before enabling an S3 Bucket Key](#).

Example policies: Using SSE-S3 and SSE-KMS with replication

The following example IAM policies show statements for using SSE-S3 and SSE-KMS with replication.

Example – Using SSE-KMS with separate destination buckets

The following example policy shows statements for using SSE-KMS with separate destination buckets.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": ["kms:Decrypt"],  
            "Effect": "Allow",  
            "Condition": {  
                "StringLike": {  
                    "kms:ViaService": "s3.source-bucket-region.amazonaws.com",  
                    "kms:EncryptionContext:aws:s3:arn": [  
                        "arn:aws:s3:::amzn-s3-demo-source-bucket/key-prefix1*"  
                    ]  
                }  
            },  
            "Resource": [  
                "List of AWS KMS key ARNs that are used to encrypt source objects."  
            ]  
        },  
        {  
            "Action": ["kms:Encrypt"],  
            "Effect": "Allow",  
            "Condition": {  
                "StringLike": {  
                    "kms:ViaService": "s3.destination-bucket-1-region.amazonaws.com",  
                    "kms:EncryptionContext:aws:s3:arn": [  
                        "arn:aws:s3:::amzn-s3-demo-destination-bucket1/key-prefix1*"  
                    ]  
                }  
            },  
            "Resource": [  
                "ARN of the destination bucket"  
            ]  
        }  
    ]  
}
```

```
        "AWS KMS key ARNs (in the same AWS Region as destination bucket 1). Used to
        encrypt object replicas created in destination bucket 1."
    ],
},
{
    "Action": ["kms:Encrypt"],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.destination-bucket-2-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket2/key-prefix1*"
            ]
        }
    },
    "Resource": [
        "AWS KMS key ARNs (in the same AWS Region as destination bucket 2). Used to
        encrypt object replicas created in destination bucket 2."
    ]
}
]
```

Example – Replicating objects created with SSE-S3 and SSE-KMS

The following is a complete IAM policy that grants the necessary permissions to replicate unencrypted objects, objects created with SSE-S3, and objects created with SSE-KMS.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action": [
                "s3:GetReplicationConfiguration",
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket"
            ]
        },
        {
            "Effect":"Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
            ]
        }
    ]
}
```

```
"Action": [
    "s3:GetObjectVersionForReplication",
    "s3:GetObjectVersionAcl"
],
"Resource": [
    "arn:aws:s3:::amzn-s3-demo-source-bucket/key-prefix1*"
]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:ReplicateObject",
        "s3:ReplicateDelete"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/key-prefix1*"
},
{
    "Action": [
        "kms:Decrypt"
    ],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.source-bucket-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/key-prefix1*"
            ]
        }
    },
    "Resource": [
        "List of the AWS KMS key ARNs that are used to encrypt source objects."
    ]
},
{
    "Action": [
        "kms:Encrypt"
    ],
    "Effect": "Allow",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.destination-bucket-region.amazonaws.com",
            "kms:EncryptionContext:aws:s3:arn": [
                "arn:aws:s3:::amzn-s3-demo-destination-bucket/prefix1*"
            ]
        }
    }
}
```

```
        }
    },
    "Resource": [
        "AWS KMS key ARNs (in the same AWS Region as the destination bucket) to use
        for encrypting object replicas"
    ]
}
]
```

Example – Replicating objects with S3 Bucket Keys

The following is a complete IAM policy that grants the necessary permissions to replicate objects with S3 Bucket Keys.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetReplicationConfiguration",
                "s3>ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectVersionForReplication",
                "s3:GetObjectVersionAcl"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/key-prefix1*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ReplicateObject",
                "s3:ReplicateDelete"
            ]
        }
    ]
}
```

```
],
  "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/key-prefix1*"
},
{
  "Action": [
    "kms:Decrypt"
  ],
  "Effect": "Allow",
  "Condition": {
    "StringLike": {
      "kms:ViaService": "s3.source-bucket-region.amazonaws.com",
      "kms:EncryptionContext:aws:s3:arn": [
        "arn:aws:s3:::amzn-s3-demo-source-bucket"
      ]
    }
  },
  "Resource": [
    "List of the AWS KMS key ARNs that are used to encrypt source objects."
  ]
},
{
  "Action": [
    "kms:Encrypt"
  ],
  "Effect": "Allow",
  "Condition": {
    "StringLike": {
      "kms:ViaService": "s3.destination-bucket-region.amazonaws.com",
      "kms:EncryptionContext:aws:s3:arn": [
        "arn:aws:s3:::amzn-s3-demo-destination-bucket"
      ]
    }
  },
  "Resource": [
    "AWS KMS key ARNs (in the same AWS Region as the destination bucket) to use
for encrypting object replicas"
  ]
}
]
```

Granting additional permissions for cross-account scenarios

In a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, you can use a KMS key to encrypt object replicas. However, the KMS key owner must grant the source bucket owner permission to use the KMS key.

Note

If you need to replicate SSE-KMS data cross-account, then your replication rule must specify a [customer managed key](#) from AWS KMS for the destination account. [AWS managed keys](#) don't allow cross-account use, and therefore can't be used to perform cross-account replication.

To grant the source bucket owner permission to use the KMS key (AWS KMS console)

1. Sign in to the AWS Management Console and open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**.
4. Choose the KMS key.
5. Under the **General configuration** section, choose the **Key policy** tab.
6. Scroll down to **Other AWS accounts**.
7. Choose **Add other AWS accounts**.

The **Other AWS accounts** dialog box appears.

8. In the dialog box, choose **Add another AWS account**. For `arn:aws:iam::`, enter the source bucket account ID.
9. Choose **Save changes**.

To grant the source bucket owner permission to use the KMS key (AWS CLI)

- For information about the `put-key-policy` AWS Command Line Interface (AWS CLI) command, see [put-key-policy](#) in the *AWS CLI Command Reference*. For information about the underlying `PutKeyPolicy` API operation, see [PutKeyPolicy](#) in the *AWS Key Management Service API Reference*.

AWS KMS transaction quota considerations

When you add many new objects with AWS KMS encryption after enabling Cross-Region Replication (CRR), you might experience throttling (HTTP 503 Service Unavailable errors). Throttling occurs when the number of AWS KMS transactions per second exceeds the current quota. For more information, see [Quotas](#) in the *AWS Key Management Service Developer Guide*.

To request a quota increase, use Service Quotas. For more information, see [Requesting a quota increase](#). If Service Quotas isn't supported in your Region, [open an AWS Support case](#).

Enabling replication for encrypted objects

By default, Amazon S3 doesn't replicate objects that are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) or dual-layer server-side encryption with AWS KMS keys (DSSE-KMS). To replicate objects encrypted with SSE-KMS or DSS-KMS, you must modify the bucket replication configuration to tell Amazon S3 to replicate these objects. This example explains how to use the Amazon S3 console and the AWS Command Line Interface (AWS CLI) to change the bucket replication configuration to enable replicating encrypted objects.

Note

When an S3 Bucket Key is enabled for the source or destination bucket, the encryption context will be the bucket's Amazon Resource Name (ARN), not the object's ARN. You must update your IAM policies to use the bucket ARN for the encryption context. For more information, see [S3 Bucket Keys and replication](#).

Note

You can use multi-Region AWS KMS keys in Amazon S3. However, Amazon S3 currently treats multi-Region keys as though they were single-Region keys, and does not use the multi-Region features of the key. For more information, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Using the S3 console

For step-by-step instructions, see [Configuring replication for buckets in the same account](#). This topic provides instructions for setting a replication configuration when the source and destination buckets are owned by the same and different AWS accounts.

Using the AWS CLI

To replicate encrypted objects with the AWS CLI, you do the following:

- Create source and destination buckets and enable versioning on these buckets.
- Create an AWS Identity and Access Management (IAM) service role that gives Amazon S3 permission to replicate objects. The IAM role's permissions include the necessary permissions to replicate the encrypted objects.
- Add a replication configuration to the source bucket. The replication configuration provides information related to replicating objects that are encrypted by using KMS keys.
- Add encrypted objects to the source bucket.
- Test the setup to confirm that your encrypted objects are being replicated to the destination bucket.

The following procedures walk you through this process.

To replicate server-side encrypted objects (AWS CLI)

To use the examples in this procedure, replace the *user input placeholders* with your own information.

1. In this example, you create both the source (*amzn-s3-demo-source-bucket*) and destination (*amzn-s3-demo-destination-bucket*) buckets in the same AWS account. You also set a credentials profile for the AWS CLI. This example uses the profile name *acctA*.

For information about setting credential profiles and using named profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide*.

2. Use the following commands to create the *amzn-s3-demo-source-bucket* bucket and enable versioning on it. The following example commands create the *amzn-s3-demo-source-bucket* bucket in the US East (N. Virginia) (us-east-1) Region.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-source-bucket \
--region us-east-1 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-source-bucket \
```

```
--versioning-configuration Status=Enabled \
--profile acctA
```

3. Use the following commands to create the *amzn-s3-demo-destination-bucket* bucket and enable versioning on it. The following example commands create the *amzn-s3-demo-destination-bucket* bucket in the US West (Oregon) (us-west-2) Region.

 **Note**

To set up a replication configuration when both *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets are in the same AWS account, you use the same profile. This example uses *acctA*. To configure replication when the buckets are owned by different AWS accounts, you specify different profiles for each.

```
aws s3api create-bucket \
--bucket amzn-s3-demo-destination-bucket \
--region us-west-2 \
--create-bucket-configuration LocationConstraint=us-west-2 \
--profile acctA
```

```
aws s3api put-bucket-versioning \
--bucket amzn-s3-demo-destination-bucket \
--versioning-configuration Status=Enabled \
--profile acctA
```

4. Next, you create an IAM service role. You will specify this role in the replication configuration that you add to the *amzn-s3-demo-source-bucket* bucket later. Amazon S3 assumes this role to replicate objects on your behalf. You create an IAM role in two steps:

- Create a service role.
- Attach a permissions policy to the role.

- a. To create an IAM service role, do the following:

- i. Copy the following trust policy and save it to a file called *s3-role-trust-policy-kmsobj.json* in the current directory on your local computer. This policy grants the

Amazon S3 service principal permissions to assume the role so that Amazon S3 can perform tasks on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

- ii. Use the following command to create the role:

```
$ aws iam create-role \  
--role-name replicationRolekmsobj \  
--assume-role-policy-document file://s3-role-trust-policy-kmsobj.json \  
--profile acctA
```

- b. Next, you attach a permissions policy to the role. This policy grants permissions for various Amazon S3 bucket and object actions.
- i. Copy the following permissions policy and save it to a file named *s3-role-permissions-policykmsobj.json* in the current directory on your local computer. You will create an IAM role and attach the policy to it later.

⚠ Important

In the permissions policy, you specify the AWS KMS key IDs that will be used for encryption of the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets. You must create two separate KMS keys for the *amzn-s3-demo-source-bucket* and *amzn-s3-demo-destination-bucket* buckets. AWS KMS keys aren't shared outside the AWS Region in which they were created.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3>ListBucket",  
                "s3:GetReplicationConfiguration",  
                "s3:GetObjectVersionForReplication",  
                "s3:GetObjectVersionAcl",  
                "s3:GetObjectVersionTagging"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket",  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateDelete",  
                "s3:ReplicateTags"  
            ],  
            "Effect": "Allow",  
            "Condition": {  
                "StringLikeIfExists": {  
                    "s3:x-amz-server-side-encryption": [  
                        "aws:kms",  
                        "AES256",  
                        "aws:kms:dsse"  
                    ],  
                    "s3:x-amz-server-side-encryption-aws-kms-key-id": [  
                        "AWS KMS key IDs(in ARN format) to use for encrypting  
                        object replicas"  
                    ]  
                }  
            },  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        },  
        {  
            "Action": [  
                "kms:Decrypt"  
            ]  
        }  
    ]  
}
```

```
        ],
        "Effect":"Allow",
        "Condition":{
            "StringLike":{
                "kms:ViaService":"s3.us-east-1.amazonaws.com",
                "kms:EncryptionContext:aws:s3:arn":[
                    "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
                ]
            }
        },
        "Resource":[
            "AWS KMS key IDs(in ARN format) used to encrypt source
objects."
        ]
    },
    {
        "Action":[
            "kms:Encrypt"
        ],
        "Effect":"Allow",
        "Condition":{
            "StringLike":{
                "kms:ViaService":"s3.us-west-2.amazonaws.com",
                "kms:EncryptionContext:aws:s3:arn":[
                    "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
                ]
            }
        },
        "Resource":[
            "AWS KMS key IDs (in ARN format) to use for encrypting object
replicas"
        ]
    }
]
```

ii. Create a policy and attach it to the role.

```
$ aws iam put-role-policy \
--role-name replicationRolekmsobj \
--policy-document file://s3-role-permissions-policykmsobj.json \
--policy-name replicationRolechangeownerPolicy \
--profile acctA
```

5. Next, add the following replication configuration to the *amzn-s3-demo-source-bucket* bucket. It tells Amazon S3 to replicate objects with the *Tax/* prefix to the *amzn-s3-demo-destination-bucket* bucket.

⚠ Important

In the replication configuration, you specify the IAM role that Amazon S3 can assume. You can do this only if you have the `iam:PassRole` permission. The profile that you specify in the CLI command must have this permission. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

```
<ReplicationConfiguration>
  <Role>IAM-Role-ARN</Role>
  <Rule>
    <Priority>1</Priority>
    <DeleteMarkerReplication>
      <Status>Disabled</Status>
    </DeleteMarkerReplication>
    <Filter>
      <Prefix>Tax</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <SourceSelectionCriteria>
      <SseKmsEncryptedObjects>
        <Status>Enabled</Status>
      </SseKmsEncryptedObjects>
    </SourceSelectionCriteria>
    <Destination>
      <Bucket>arn:aws:s3:::amzn-s3-demo-destination-bucket</Bucket>
      <EncryptionConfiguration>
        <ReplicaKmsKeyID>AWS KMS key IDs to use for encrypting object replicas</ReplicaKmsKeyID>
      </EncryptionConfiguration>
    </Destination>
  </Rule>
</ReplicationConfiguration>
```

To add a replication configuration to the *amzn-s3-demo-source-bucket* bucket, do the following:

- a. The AWS CLI requires you to specify the replication configuration as JSON. Save the following JSON in a file (*replication.json*) in the current directory on your local computer.

```
{  
    "Role": "IAM-Role-ARN",  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Priority": 1,  
            "DeleteMarkerReplication": {  
                "Status": "Disabled"  
            },  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
                "EncryptionConfiguration": {  
                    "ReplicaKmsKeyID": "AWS KMS key IDs (in ARN format) to use for  
                    encrypting object replicas"  
                }  
            },  
            "SourceSelectionCriteria": {  
                "SseKmsEncryptedObjects": {  
                    "Status": "Enabled"  
                }  
            }  
        }  
    ]  
}
```

- b. Edit the JSON to provide values for the *amzn-s3-demo-destination-bucket* bucket, *AWS KMS key IDs (in ARN format)*, and *IAM-role-ARN*. Save the changes.
- c. Use the following command to add the replication configuration to your *amzn-s3-demo-source-bucket* bucket. Be sure to provide the *amzn-s3-demo-source-bucket* bucket name.

```
$ aws s3api put-bucket-replication \  
--replication-configuration file://replication.json \  
--bucket amzn-s3-demo-source-bucket \  

```

```
--profile acctA
```

6. Test the configuration to verify that encrypted objects are replicated. In the Amazon S3 console, do the following:
 - a. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. In the *amzn-s3-demo-source-bucket* bucket, create a folder named *Tax*.
 - c. Add sample objects to the folder. Be sure to choose the encryption option and specify your KMS key to encrypt the objects.
 - d. Verify that the *amzn-s3-demo-destination-bucket* bucket contains the object replicas and that they are encrypted by using the KMS key that you specified in the configuration. For more information, see [the section called “Getting replication status”](#).

Using the AWS SDKs

For a code example that shows how to add a replication configuration, see [Using the AWS SDKs](#). You must modify the replication configuration appropriately.

Replicating metadata changes with replica modification sync

Amazon S3 replica modification sync can help you keep object metadata such as tags, access control lists (ACLs), and Object Lock settings replicated between replicas and source objects. By default, Amazon S3 replicates metadata from the source objects to the replicas only. When replica modification sync is enabled, Amazon S3 replicates metadata changes made to the replica copies back to the source object, making the replication bidirectional (two-way replication).

Enabling replica modification sync

You can use Amazon S3 replica modification sync with new or existing replication rules. You can apply it to an entire bucket or to objects that have a specific prefix.

To enable replica modification sync by using the Amazon S3 console, see [Examples for configuring live replication](#). This topic provides instructions for enabling replica modification sync in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replica modification sync by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the bucket containing the replicas with

ReplicaModifications enabled. To set up two-way replication, create a replication rule from the source bucket (*amzn-s3-demo-source-bucket*) to the bucket containing the replicas (*amzn-s3-demo-destination-bucket*). Then, create a second replication rule from the bucket containing the replicas (*amzn-s3-demo-destination-bucket*) to the source bucket (*amzn-s3-demo-source-bucket*). The source and destination buckets can be in the same or different AWS Regions.

 **Note**

You must enable replica modification sync on both the source and destination buckets to replicate replica metadata changes like object access control lists (ACLs), object tags, or Object Lock settings on the replicated objects. Like all replication rules, you can apply these rules to the entire bucket or to a subset of objects filtered by prefix or object tags.

In the following example configuration, Amazon S3 replicates metadata changes under the prefix *Tax* to the bucket *amzn-s3-demo-source-bucket*, which contains the source objects.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "SourceSelectionCriteria": {  
                "ReplicaModifications": {  
                    "Status": "Enabled"  
                }  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            },  
            "Priority": 1  
        }  
    ],  
    "Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules by using the AWS CLI, see [Configuring replication for buckets in the same account](#).

Replicating delete markers between buckets

By default, when S3 Replication is enabled and an object is deleted in the source bucket, Amazon S3 adds a delete marker in the source bucket only. This action helps protect data in the destination buckets from accidental or malicious deletions. If you have *delete marker replication* enabled, these markers are copied to the destination buckets, and Amazon S3 behaves as if the object was deleted in both the source and destination buckets. For more information about how delete markers work, see [Working with delete markers](#).

Note

- Delete marker replication isn't supported for tag-based replication rules. Delete marker replication also doesn't adhere to the 15-minute service-level agreement (SLA) that's granted when you're using S3 Replication Time Control (S3 RTC).
- If you're not using the latest replication configuration XML version, delete operations affect replication differently. For more information, see [How delete operations affect replication](#).
- If you enable delete marker replication and your source bucket has an S3 Lifecycle expiration rule, the delete markers added by the S3 Lifecycle expiration rule won't be replicated to the destination bucket.

Enabling delete marker replication

You can start using delete marker replication with a new or existing replication rule. You can apply delete marker replication to an entire bucket or to objects that have a specific prefix.

To enable delete marker replication by using the Amazon S3 console, see [Using the S3 console](#). This topic provides instructions for enabling delete marker replication in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable delete marker replication by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with `DeleteMarkerReplication` enabled, as shown in the following example configuration.

In the following example replication configuration, delete markers are replicated to the destination bucket *amzn-s3-demo-destination-bucket* for objects under the prefix *Tax*.

```
{  
    "Rules": [  
        {  
            "Status": "Enabled",  
            "Filter": {  
                "Prefix": "Tax"  
            },  
            "DeleteMarkerReplication": {  
                "Status": "Enabled"  
            },  
            "Destination": {  
                "Bucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket"  
            },  
            "Priority": 1  
        }  
    ],  
    "Role": "IAM-Role-ARN"  
}
```

For full instructions on creating replication rules through the AWS CLI, see [Configuring replication for buckets in the same account](#).

Managing or pausing live replication

Live replication is the automatic, asynchronous copying of objects across buckets in the same or different AWS Regions. After you set up your replication configuration, Amazon S3 replicates newly created objects and object updates from a source bucket to one or more specified destination buckets.

You use the Amazon S3 console to add replication rules to the source bucket. Replication rules define the source bucket objects to replicate and the destination bucket or buckets where the replicated objects are stored. For more information about replication, see [Replicating objects within and across Regions](#).

You can manage replication rules on the **Replication** page in the Amazon S3 console. You can add, view, edit, enable, disable, or delete replication rules. You can also change the priority of your replication rules. For information about adding replication rules to a bucket, see [Using the S3 console](#).

To manage the replication rules for a bucket by using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. On the **General purpose buckets** tab, choose the name of the bucket that you want.
4. Choose the **Management** tab, and then scroll down to **Replication rules**.
5. You can change your replication rules in the following ways:
 - To enable or disable a replication rule, choose the option button to the left of the rule. On the **Actions** menu, choose **Enable rule** or **Disable rule**. You can also disable, enable, or delete all the rules in the bucket from the **Actions** menu.

 **Note**

If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't replicated while the rule was disabled are *not* automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see [the section called "Replicating existing objects"](#).

- To change the priority of a rule, choose the option button to the left of the rule, and then choose **Edit rule**.

You set rule priorities to avoid conflicts caused by objects that are included in the scope of more than one rule. In the case of overlapping rules, Amazon S3 uses the rule priority to determine which rule to apply. The higher the number, the higher the priority. For more information about rule priority, see [Replication configuration file elements](#).

Pausing or stopping replication

To temporarily pause replication and have it automatically resume later, you can use the `aws:s3:bucket-pause-replication` action in AWS Fault Injection Service. For more information, see [aws:s3:bucket-pause-replication](#) and [Pause S3 Replication](#) in the *AWS Fault Injection Service User Guide*.

To stop replication in Amazon S3, we recommend disabling your replication rules. If you disable a replication rule and then later re-enable the rule, any new or changed objects that weren't

replicated while the rule was disabled are *not* automatically replicated when the rule is re-enabled. To replicate those objects, you must use S3 Batch Replication. For more information, see [the section called “Replicating existing objects”](#).

Replication will also stop if you remove the AWS Identity and Access Management (IAM) role, the AWS Key Management Service (AWS KMS) permissions, or the bucket policy permissions that grant Amazon S3 the required permissions. However, we don't recommend these approaches because they cause replication to fail. Amazon S3 reports the replication status for affected objects as FAILED. If permissions are later restored, objects marked as FAILED are *not* automatically replicated. To replicate those objects, you must use S3 Batch Replication.

Replicating existing objects with Batch Replication

S3 Batch Replication differs from live replication, which continuously and automatically replicates new objects across Amazon S3 buckets. Instead, S3 Batch Replication occurs on demand on existing objects. You can use S3 Batch Replication to replicate the following types of objects:

- Objects that existed before a replication configuration was in place
- Objects that have previously been replicated
- Objects that have failed replication

You can replicate these objects on demand by using a Batch Operations job.

To get started with Batch Replication, you can:

- **Initiate Batch Replication for a new replication rule or destination** – You can create a one-time Batch Replication job when you're creating the first rule in a new replication configuration or when you're adding a new destination bucket to an existing configuration through the Amazon S3 console.
- **Initiate Batch Replication for an existing replication configuration** – You can create a new Batch Replication job by using S3 Batch Operations through the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

When the Batch Replication job finishes, you receive a completion report. For more information about how to use this report to examine the job, see [Tracking job status and completion reports](#).

S3 Batch Replication considerations

Before using S3 Batch Replication, review the following list of considerations:

- Your source bucket must have an existing replication configuration. To enable replication, see [Setting up live replication overview](#) and [Examples for configuring live replication](#).
- If you have S3 Lifecycle configured for your bucket, we recommend disabling your lifecycle rules while the Batch Replication job is active. Doing so helps ensure parity between the source and destination buckets. Otherwise, these buckets could diverge, and the destination bucket won't be an exact replica of the source bucket. For example, consider the following scenario:
 - Your source bucket has multiple versions of an object and a delete marker on that object.
 - Your source and destination buckets have a lifecycle configuration to remove expired delete markers.

In this scenario, Batch Replication might replicate the delete marker to the destination bucket before replicating the object versions. This behavior could result in your lifecycle configuration marking the delete marker as expired and the delete marker being removed from the destination bucket before the object versions are replicated.

- The AWS Identity and Access Management (IAM) role that you specify to run the Batch Operations job must have the necessary permissions to perform the underlying Batch Replication operation. For more information about creating IAM roles, see [Configuring an IAM role for S3 Batch Replication](#).
- Batch Replication requires a manifest, which can be generated by Amazon S3. The generated manifest must be stored in the same AWS Region as the source bucket. If you choose not to generate the manifest, you can supply an Amazon S3 Inventory report or CSV file that contains the objects that you want to replicate. For more information, see [the section called "Specifying a manifest for a Batch Replication job"](#).
- Batch Replication doesn't support re-replicating objects that were deleted by specifying the version ID of the object from the destination bucket. To re-replicate these objects, you can copy the source objects in place with a Batch Copy job. Copying those objects in place creates new versions of the objects in the source bucket and automatically initiates replication to the destination bucket. Deleting and recreating the destination bucket doesn't initiate replication.

For more information about Batch Copy, see [Examples that use Batch Operations to copy objects](#).

- If you're using a replication rule on the source bucket, make sure to [update your replication configuration](#) by granting the IAM role that's attached to the replication rule the proper

permissions to replicate objects. This IAM role must have the necessary permissions to perform replication on both the source and destination buckets.

- If you submit multiple Batch Replication jobs for the same bucket within a short time frame, Amazon S3 runs those jobs concurrently.
- If you submit multiple Batch Replication jobs for two different buckets, be aware that Amazon S3 might not run all jobs concurrently. If you exceed the number of Batch Replication jobs that can run at one time on your account, Amazon S3 pauses the lower priority jobs to work on the higher priority ones. After the higher priority jobs are completed, any paused jobs become active again.
- Batch Replication isn't supported for objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.
- To batch replicate S3 Intelligent-Tiering objects that are stored in the Archive Access or Deep Archive Access storage tiers, you must first initiate a [restore](#) request and wait until the objects are moved to the Frequent Access tier.

Specifying a manifest for a Batch Replication job

A manifest is an Amazon S3 object that contains the object keys that you want Amazon S3 to act upon. If you want to create a Batch Replication job, you must supply either a user-generated manifest or have Amazon S3 generate a manifest based on your replication configuration.

If you supply a user-generated manifest, it must be in the form of an Amazon S3 Inventory report or a CSV file. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID that's specified in the manifest will be replicated. To learn more about specifying a manifest, see [Specifying a manifest](#).

If you choose to have Amazon S3 generate a manifest file on your behalf, the objects listed use the same source bucket, prefix, and tags as your replication configurations on the source bucket. With a generated manifest, Amazon S3 replicates all eligible versions of your objects.

Note

If you choose to have Amazon S3 generate the manifest, the manifest must be stored in the same AWS Region as the source bucket.

Filters for a Batch Replication job

When creating your Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the `ObjectReplicationStatuses` value, by providing one or more of the following values:

- "NONE" – Indicates that Amazon S3 has never attempted to replicate the object before.
- "FAILED" – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- "COMPLETED" – Indicates that Amazon S3 has successfully replicated the object before.
- "REPLICA" – Indicates that this object is a replica that Amazon S3 has replicated from another source bucket.

For more information about replication statuses, see [Getting replication status information](#).

If you don't filter your Batch Replication job, Batch Operations attempts to replicate all objects (no matter their `ObjectReplicationStatus`) in your manifest that match the rules in your replication configuration, except for certain objects that aren't replicated by default. For more information, see [the section called "What isn't replicated with replication configurations?"](#)

Depending on your goal, you might set `ObjectReplicationStatuses` to one or more of the following values:

- To replicate only existing objects that have never been replicated, only include "NONE".
- To retry replicating only objects that previously failed to replicate, only include "FAILED".
- To both replicate existing objects and retry replicating objects that previously failed to replicate, include both "NONE" and "FAILED".
- To backfill a destination bucket with objects that have been replicated to another destination, include "COMPLETED".
- To replicate objects that were previously replicated, include "REPLICA".

Batch Replication completion report

When you create a Batch Replication job, you can request a CSV completion report. This report shows the objects, replication success or failure codes, outputs, and descriptions. For more information about job tracking and completion reports, see [Completion reports](#).

For a list of replication failure codes and descriptions, see [Amazon S3 replication failure reasons](#).

For information about troubleshooting Batch Replication, see [Batch Replication errors](#).

Getting started with Batch Replication

To learn more about how to use Batch Replication, see [Tutorial: Replicating existing objects in your Amazon S3 buckets with S3 Batch Replication](#).

Configuring an IAM role for S3 Batch Replication

Because Amazon S3 Batch Replication is a type of Batch Operations job, you must create an AWS Identity and Access Management (IAM) role to grant Batch Operations permissions to perform actions on your behalf. You also must attach a Batch Replication IAM policy to the Batch Operations IAM role.

Use the following procedures to create a policy and an IAM role that give Batch Operations permission to initiate a Batch Replication job.

To create a policy for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Policies**.
3. Choose **Create policy**.
4. On the **Specify permissions** page, choose **JSON**.
5. Insert one of the following policies, depending on whether your manifest is generated by Amazon S3 or whether you are supplying your own manifest. For more information about manifests, see [Specifying a manifest for a Batch Replication job](#).

Before using these policies, replace the *user input placeholders* in the following policies with the names of your replication source bucket, manifest bucket, and completion report bucket.

Note

Your IAM role for Batch Replication needs different permissions, depending on whether you are generating a manifest or supplying one, so make sure that you choose the appropriate policy from the following examples.

Policy if using and storing an Amazon S3 generated manifest

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "s3:InitiateReplication"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"  
            ]  
        },  
        {  
            "Action": [  
                "s3:GetReplicationConfiguration",  
                "s3:PutInventoryConfiguration"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-source-bucket"  
            ]  
        },  
        {  
            "Action": [  
                "s3:GetObject",  
                "s3:GetObjectVersion"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*",  
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"  
            ]  
        }  
    ]  
}
```

```
        ]
    }
]
}
```

Policy if using a user-supplied manifest

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:InitiateReplication"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        },
        {
            "Action": [
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-manifest-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-completion-report-bucket/*"
            ]
        }
    ]
}
```

6. Choose **Next**.
7. Specify a name for the policy, and then choose **Create policy**.

To create an IAM role for Batch Replication

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access management**, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service** as the type of trusted entity. In the **Use case** section, choose **S3** as the service, and **S3 Batch Operations** as the use case.
5. Choose **Next**. The **Add permissions** page appears. In the search box, search for the policy that you created in the preceding procedure. Select the checkbox next to the policy name, then choose **Next**.
6. On the **Name, review, and create** page, specify a name for your IAM role.
7. In the **Step 1: Trust identities** section, verify that your IAM role is using the following trust policy:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "batchoperations.s3.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

8. In the **Step 2: Add permissions** section, verify that your IAM role is using the policy that you created earlier.
9. Choose **Create role**.

Create a Batch Replication job for new replication rules or destinations

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is

created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

When you create the first rule in a new live replication configuration or add a new destination bucket to an existing replication configuration through the Amazon S3 console, you can optionally create a Batch Replication job. You can use this Batch Replication job to replicate existing objects in the source bucket to the destination bucket.

To use Batch Replication for an existing configuration without adding a new destination bucket, see [Create a Batch Replication job for existing replication rules](#).

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

Using Batch Replication for a new replication rule or destination through the Amazon S3 console

When you create the first rule in a new replication configuration or add a new destination bucket to an existing configuration through the Amazon S3 console, you can choose to create a Batch Replication job to replicate existing objects in the source bucket.

To create a Batch Replication job when creating or updating a replication configuration

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that contains the objects that you want to replicate.
4. To create a new replication rule or edit an existing rule, choose the **Management** tab, and scroll down to **Replication rules**:
 - To create a new replication rule, choose **Create replication rule**. For examples of how to set up a basic replication rule, see [Examples for configuring live replication](#).
 - To edit an existing replication rule, select the option button next to the rule name, and then choose **Edit rule**.

5. Create your new replication rule or edit the destination for your existing replication rule, and choose **Save**.

After you create the first rule in a new replication configuration or edit an existing configuration to add a new destination, a **Replicate existing objects?** dialog appears, giving you the option to create a Batch Replication job.

6. If you want to create and run this job now, choose **Yes, replicate existing objects**.

If you want to create a Batch Replication job at a later time, choose **No, do not replicate existing objects**.

7. If you chose **Yes, replicate existing objects**, the **Create Batch Operations job** page appears. The S3 Batch Replication job has the following settings:

Job run options

If you want the S3 Batch Replication job to run immediately, choose **Automatically run the job when it's ready**. If you want to run the job at a later time, choose **Wait to run the job when it's ready**.

Note

If you choose **Automatically run the job when it's ready**, you won't be able to create and save a Batch Operations manifest. To save the Batch Operations manifest, choose **Wait to run the job when it's ready**.

Batch Operations manifest

If you chose **Wait to run the job when it's ready**, the **Batch Operations manifest** section appears. The manifest is a list of all of the objects that you want to run the specified action on. You can choose to save the manifest. Similar to S3 Inventory files, the manifest will be saved as a CSV file and stored in a bucket. To learn more about Batch Operations manifests, see [Specifying a manifest](#).

Completion report

S3 Batch Operations executes one task for each object specified in the manifest. Completion reports provide an easy way to view the results of your tasks in a consolidated

format with no additional setup required. You can request a completion report for all tasks or only for failed tasks. To learn more about completion reports, see [Completion reports](#).

Permissions

One of the most common causes of replication failures is insufficient permissions in the provided AWS Identity and Access Management (IAM) role. For information about creating this role, see [Configuring an IAM role for S3 Batch Replication](#). Make sure that you create or choose an IAM role that has the required permissions for Batch Replication.

8. Choose **Save**.

Create a Batch Replication job for existing replication rules

In Amazon S3, live replication doesn't replicate any objects that already existed in your source bucket before you created a replication configuration. Live replication automatically replicates only new and updated objects that are written to the bucket after the replication configuration is created. To replicate already existing objects, you can use S3 Batch Replication to replicate these objects on demand.

You can configure S3 Batch Replication for an existing replication configuration by using the AWS SDKs, AWS Command Line Interface (AWS CLI), or the Amazon S3 console. For an overview of Batch Replication, see [Replicating existing objects with Batch Replication](#).

When the Batch Replication job finishes, you receive a completion report. For more information about how to use the report to examine the job, see [Tracking job status and completion reports](#).

Prerequisites

Before creating your Batch Replication job, you must create a Batch Operations AWS Identity and Access Management (IAM) role to grant Amazon S3 permissions to perform actions on your behalf. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. Verify that the **AWS Region** section shows the Region where you want to create your job.

5. In the **Manifest** section, specify the manifest format that you want to use. The manifest is a list of all of the objects that you want to run the specified action on. To learn more about Batch Operations manifests, see [Specifying a manifest](#).

- If you have a manifest prepared, choose **S3 inventory report (manifest.json)** or **CSV**. If your manifest is in a versioned bucket, you can specify the version ID for the manifest. If you don't specify a version ID, Batch Operations uses the current version of your manifest. For more information about creating a manifest, see [Specifying a manifest](#).

 **Note**

If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. For more information, see [Specifying a manifest](#).

- To create a manifest based on your replication configuration, choose **Create manifest using S3 Replication configuration**. Then choose the source bucket of your replication configuration.
6. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can include additional filters, such as the object creation date and replication status. For examples of how to filter by replication status, see [Specifying a manifest for a Batch Replication job](#).
 7. (Optional) If you chose **Create manifest using S3 Replication configuration**, you can save the generated manifest. To save this manifest, select **Save Batch Operations manifest**. Then specify the destination bucket for the manifest and choose whether to encrypt the manifest.

 **Note**

The generated manifest must be stored in the same AWS Region as the source bucket.

8. Choose **Next**.
9. On the **Operations** page, choose **Replicate**, then choose **Next**.
10. (Optional) Provide a **Description**.
11. Adjust the **Priority** of the job if needed. Higher numbers indicate higher priority. Amazon S3 attempts to run higher priority jobs before lower priority jobs. For more information about job priority, see [Assigning job priority](#).
12. (Optional) Generate a completion report. To generate this report, select **Generate completion report**.

If you choose to generate a completion report, you must choose either to report **Failed tasks only** or **All tasks**, and provide a destination bucket for the report.

13. In the **Permissions** section, make sure that you choose an IAM role that has the required permissions for Batch Replication. One of the most common causes of replication failures is insufficient permissions in the provided IAM role. For information about creating this role, see [Configuring an IAM role for S3 Batch Replication](#).
14. (Optional) Add job tags to the Batch Replication job.
15. Choose **Next**.
16. Review your job configuration, and then choose **Create job**.

Using the AWS CLI with an S3 manifest

The following example `create-job` command creates an S3 Batch Replication job by using an S3 generated manifest for the AWS account **111122223333**. This example replicates existing objects and objects that previously failed to replicate. For information about filtering by replication status, see [Specifying a manifest for a Batch Replication job](#).

To use this command, replace the *user input placeholders* with your own information. Replace the IAM role `role/batch-Replication-IAM-policy` with the IAM role that you previously created. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

```
aws s3control create-job --account-id 111122223333 \
--operation '["S3ReplicateObject":{}]' \
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket", \
"Prefix":"batch-replication-report", \
"Format":"Report_CSV_20180820","Enabled":true,"ReportScope":"AllTasks"}' \
--manifest-generator '{"S3JobManifestGenerator": {"ExpectedBucketOwner": \
"111122223333", \
"SourceBucket": "arn:aws:s3:::amzn-s3-demo-source-bucket", \
"EnableManifestOutput": false, "Filter": {"EligibleForReplication": true, \
"ObjectReplicationStatuses": ["NONE","FAILED"]}}}' \
--priority 1 \
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \
--no-confirmation-required \
--region source-bucket-region
```

Note

You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following `describe-job` command. To use this command, replace the *user input placeholders* with your own information.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Using the AWS CLI with a user-provided manifest

The following example creates an S3 Batch Replication job by using a user-defined manifest for AWS account *111122223333*. If the objects in your manifest are in a versioned bucket, you must specify the version IDs for the objects. Only the object with the version ID specified in the manifest will be replicated. For more information about creating a manifest, see [Specifying a manifest](#).

To use this command, replace the *user input placeholders* with your own information. Replace the IAM role `role/batch-Replication-IAM-policy` with the IAM role that you previously created. For more information, see [Configuring an IAM role for S3 Batch Replication](#).

```
aws s3control create-job --account-id 111122223333 \  
--operation '{"S3ReplicateObject":{}}' \  
--report '{"Bucket":"arn:aws:s3:::amzn-s3-demo-completion-report-bucket",\  
"Prefix":"batch-replication-report", \  
"Format":"Report_CSV_20180820", "Enabled":true, "ReportScope":"AllTasks"}' \  
--manifest '{"Spec":{"Format":"S3BatchOperations_CSV_20180820", \  
"Fields":["Bucket", "Key", "VersionId"]}, \  
"Location":{"ObjectArn":"arn:aws:s3:::amzn-s3-demo-manifest-bucket/manifest.csv", \  
"ETag":"Manifest Etag"}' \  
--priority 1 \  
--role-arn arn:aws:iam::111122223333:role/batch-Replication-IAM-policy \  
--no-confirmation-required \  
--region source-bucket-region
```

Note

You must initiate the job from the same AWS Region as the replication source bucket.

After you have successfully initiated a Batch Replication job, you receive the job ID as the response. You can monitor this job by using the following describe-job command.

```
aws s3control describe-job --account-id 111122223333 --job-id job-id --region source-bucket-region
```

Troubleshooting replication

This section lists troubleshooting tips for Amazon S3 Replication and information about S3 Batch Replication errors.

Topics

- [Troubleshooting tips for S3 Replication](#)
- [Batch Replication errors](#)

Troubleshooting tips for S3 Replication

If object replicas don't appear in the destination bucket after you configure replication, use these troubleshooting tips to identify and fix issues.

- The majority of objects replicate within 15 minutes. The time that it takes Amazon S3 to replicate an object depends on several factors, including the source and destination Region pair, and the size of the object. For large objects, replication can take up to several hours. For visibility into replication times, you can use [S3 Replication Time Control \(S3 RTC\)](#).

If the object that is being replicated is large, wait a while before checking to see whether it appears in the destination. You can also check the replication status of the source object. If the object replication status is PENDING, Amazon S3 hasn't completed the replication. If the object replication status is FAILED, check the replication configuration that's set on the source bucket.

Additionally, to receive information about failures during replication, you can set up Amazon S3 Event Notifications replication to receive failure events. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

- To check the replication status of an object, you can call the HeadObject API operation. The HeadObject API operation returns the PENDING, COMPLETED, or FAILED replication status of an object. In a response to a HeadObject API call, the replication status is returned in the x-amz-replication-status header.

Note

To run HeadObject, you must have read access to the object that you're requesting.

A HEAD request has the same options as a GET request, without performing a GET operation. For example, to run a HeadObject request by using the AWS Command Line Interface (AWS CLI), you can run the following command. Replace the *user input placeholders* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-source-bucket --key index.html
```

- If HeadObject returns objects with a FAILED replication status, you can use S3 Batch Replication to replicate those failed objects. For more information, see [the section called "Replicating existing objects"](#). Alternatively, you can re-upload the failed objects to the source bucket, which will initiate replication for the new objects.
- In the replication configuration on the source bucket, verify the following:
 - The Amazon Resource Name (ARN) of the destination bucket is correct.
 - The key name prefix is correct. For example, if you set the configuration to replicate objects with the prefix Tax, then only objects with key names such as Tax/document1 or Tax/document2 are replicated. An object with the key name document3 is not replicated.
 - The status of the replication rule is Enabled.
- Verify that versioning hasn't been suspended on any bucket in the replication configuration. Both the source and destination buckets must have versioning enabled.
- If a replication rule is set to **Change object ownership to the destination bucket owner**, then the AWS Identity and Access Management (IAM) role that's used for replication must have the `s3:ObjectOwnerOverrideToBucketOwner` permission. This permission is granted on the resource (in this case, the destination bucket). For example, the following Resource statement shows how to grant this permission on the destination bucket:

```
{  
    "Effect": "Allow",  
    "Action": [  
        "s3:ObjectOwnerOverrideToBucketOwner"  
    ],  
    "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
}
```

- If the destination bucket is owned by another account, the owner of the destination bucket must also grant the `s3:ObjectOwnerOverrideToBucketOwner` permission to the source bucket owner through the destination bucket policy. To use the following example bucket policy, replace the *user input placeholders* with your own information:

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1644945280205",  
    "Statement": [  
        {  
            "Sid": "Stmt1644945277847",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"  
            },  
            "Action": [  
                "s3:ReplicateObject",  
                "s3:ReplicateTags",  
                "s3:ObjectOwnerOverrideToBucketOwner"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"  
        }  
    ]  
}
```

Note

If the destination bucket's object ownership settings include **Bucket owner enforced**, then you don't need to update the setting to **Change object ownership to the destination bucket owner** in the replication rule. The object ownership change will occur by default. For more information about changing replica ownership, see [Changing the replica owner](#).

- If you're setting the replication configuration in a cross-account scenario, where the source and destination buckets are owned by different AWS accounts, the destination buckets can't be configured as a Requester Pays bucket. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).
- If a bucket's source objects are encrypted by using server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), then the replication rule must be configured to

include AWS KMS-encrypted objects. Make sure to select **Replicate objects encrypted with AWS KMS** under your **Encryption** settings in the Amazon S3 console. Then, select an AWS KMS key for encrypting the destination objects.

Note

If the destination bucket is in a different account, specify an AWS KMS customer managed key that is owned by the destination account. Don't use the default Amazon S3 managed key (aws/s3). Using the default key encrypts the objects with the Amazon S3 managed key that's owned by the source account, preventing the object from being shared with another account. As a result, the destination account won't be able to access the objects in the destination bucket.

To use an AWS KMS key that belongs to the destination account to encrypt the destination objects, the destination account must grant the `kms:GenerateDataKey` and `kms:Encrypt` permissions to the replication role in the KMS key policy. To use the following example statement in your KMS key policy, replace the *user input placeholders* with your own information:

```
{  
    "Sid": "AllowS3ReplicationSourceRoleToUseTheKey",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": "arn:aws:iam::123456789101:role/s3-replication-role"  
    },  
    "Action": ["kms:GenerateDataKey", "kms:Encrypt"],  
    "Resource": "*"  
}
```

If you use an asterisk (*) for the Resource statement in the AWS KMS key policy, the policy grants permission to use the KMS key to only the replication role. The policy doesn't allow the replication role to elevate its permissions.

By default, the KMS key policy grants the root user full permissions to the key. These permissions can be delegated to other users in the same account. Unless there are Deny statements in the source KMS key policy, using an IAM policy to grant the replication role permissions to the source KMS key is sufficient.

Note

KMS key policies that restrict access to specific CIDR ranges, virtual private cloud (VPC) endpoints, or S3 access points can cause replication to fail.

If either the source or destination KMS keys grant permissions based on the encryption context, confirm that Amazon S3 Bucket Keys are turned on for the buckets. If the buckets have S3 Bucket Keys turned on, the encryption context must be the bucket-level resource, like this:

```
"kms:EncryptionContext:arn:aws:arn": [
    "arn:aws:s3:::amzn-s3-demo-source-bucket"
]
"kms:EncryptionContext:arn:aws:arn": [
    "arn:aws:s3:::amzn-s3-demo-destination-bucket"
]
```

In addition to the permissions granted by the KMS key policy, the source account must add the following minimum permissions to the replication role's IAM policy:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "Source-KMS-Key-ARN"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",
        "kms:Encrypt"
    ],
    "Resource": [
        "Destination-KMS-Key-ARN"
    ]
}
```

For more information about how to replicate objects that are encrypted with AWS KMS, see [Replicating encrypted objects](#).

- If the destination bucket is owned by another AWS account, verify that the bucket owner has a bucket policy on the destination bucket that allows the source bucket owner to replicate objects. For an example, see [Configuring replication for buckets in different accounts](#).
- To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are s3:GetObjectRetention and s3:GetObjectLegalHold. If the role has an s3:Get* permission statement, that statement satisfies the requirement. For more information, see [the section called “Using Object Lock with S3 Replication”](#).
- If your objects still aren't replicating after you've validated the permissions, check for any explicit Deny statements in the following locations:
 - Deny statements in the source or destination bucket policies. Replication fails if the bucket policy denies access to the replication role for any of the following actions:

Source bucket:

```
"s3:GetReplicationConfiguration",
"s3>ListBucket",
"s3:GetObjectVersionForReplication",
"s3:GetObjectVersionAcl",
"s3:GetObjectVersionTagging"
```

Destination buckets:

```
"s3:ReplicateObject",
"s3:ReplicateDelete",
"s3:ReplicateTags"
```

- Deny statements or permissions boundaries attached to the IAM role can cause replication to fail.
- Deny statements in AWS Organizations service control policies (SCPs) that are attached to either the source or destination accounts can cause replication to fail.
- Deny statements in AWS Organizations resource control policies (RCPs) that are attached to either the source or destination buckets can cause replication to fail.

- If an object replica doesn't appear in the destination bucket, the following issues might have prevented replication:
 - Amazon S3 doesn't replicate an object in a source bucket that is a replica created by another replication configuration. For example, if you set a replication configuration from bucket A to bucket B to bucket C, Amazon S3 doesn't replicate object replicas in bucket B to bucket C.
 - A source bucket owner can grant other AWS accounts permission to upload objects. By default, the source bucket owner doesn't have permissions for the objects created by other accounts. The replication configuration replicates only the objects for which the source bucket owner has access permissions. To avoid this problem, the source bucket owner can grant other AWS accounts permissions to create objects conditionally, requiring explicit access permissions on those objects. For an example policy, see [Grant cross-account permissions to upload objects while ensuring that the bucket owner has full control](#).
- Suppose that in the replication configuration, you add a rule to replicate a subset of objects that have a specific tag. In this case, you must assign the specific tag key and value at the time the object is created in order for Amazon S3 to replicate the object. If you first create an object and then add the tag to the existing object, Amazon S3 doesn't replicate the object.
- Use Amazon S3 Event Notifications to notify you of instances when objects don't replicate to their destination AWS Region. Amazon S3 Event Notifications are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [Receiving replication failure events with Amazon S3 Event Notifications](#).

You can also view replication failure reasons by using Amazon S3 Event Notifications. To review the list of failure reasons, see [Amazon S3 replication failure reasons](#).

Batch Replication errors

To troubleshoot objects that aren't replicating to the destination bucket, check the different types of permissions for your buckets, replication role, and IAM role that's used to create the Batch Replication job. Also, make sure to check the Block Public Access settings and S3 Object Ownership settings for your buckets.

For additional troubleshooting tips for working with Batch Operations, see [the section called "Troubleshooting Batch Operations"](#).

While using Batch Replication, you might encounter one of these errors:

- Manifest generation found no keys matching the filter criteria.

This error occurs for one of the following reasons:

- When objects in the source bucket are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

To use Batch Replication on these objects, first restore them to the S3 Standard storage class by using a **Restore** (`S3InitiateRestoreObjectOperation`) operation in a Batch Operations job. For more information, see [Restoring an archived object](#) and [Restore objects \(Batch Operations\)](#). After you've restored the objects, you can replicate them by using a Batch Replication job.

- When the provided filter criteria doesn't match any valid objects in the source bucket.

Verify and correct the filter criteria. For example, in the Batch Replication rule, the filter criteria is looking for all objects in the source bucket with the prefix Tax/. If the prefix name was entered inaccurately, with a slash in the beginning and the end /Tax/ instead of only at the end, then no S3 objects were found. To resolve the error, correct the prefix, in this case, from / Tax/ to Tax/ in the replication rule.

- Batch operation status is failed with reason: The job report could not be written to your report bucket.

This error occurs if the IAM role that's used for the Batch Operations job is unable to put the completion report into the location that was specified when you created the job. To resolve this error, check that the IAM role has the `s3:PutObject` permission for the bucket where you want to save the Batch Operations completion report. We recommend delivering the report to a bucket different from the source bucket.

For additional tips on resolving this error, see [the section called “Job report isn't delivered when there is a permissions issue or a retention mode is enabled”](#).

- Batch operation is completed with failures and Total failed is not 0.

This error occurs if there are insufficient object permissions issues with the Batch Replication job that is running. If you're using a replication rule for your Batch Replication job, make sure that the IAM role that's used for replication has the proper permissions to access objects from either the source or destination bucket. You can also check the [Batch Replication completion report](#) to review the specific [Amazon S3 replication failure reason](#).

- Batch job ran successfully but the number of objects expected in destination bucket is not the same.

This error occurs when there's a mismatch between the objects listed in the manifest that's supplied in the Batch Replication job and the filters that you selected when you created the job. You might also receive this message when the objects in your source bucket don't match any replication rules and aren't included in the generated manifest.

Batch Operations failures occur after adding a new replication rule to an existing replication configuration

Batch Operations attempts to perform existing object replication for every rule in the source bucket's replication configuration. If there are problems with any of the existing replication rules, failures might occur.

The Batch Operations job's completion report explains the job failure reasons. For a list of common errors, see [Amazon S3 replication failure reasons](#).

Monitoring replication with metrics, event notifications, and statuses

You can monitor your live replication configurations and your S3 Batch Replication jobs through the following mechanisms:

- **S3 Replication metrics** – When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at the replication rule level. You can view S3 Replication metrics through the Amazon S3 console and the Amazon CloudWatch console. In the Amazon S3 console, you can view these metrics in the source bucket's **Metrics** tab. For more information about S3 Replication metrics, see [the section called "Using S3 Replication metrics"](#).
- **S3 Storage Lens metrics** – In addition to S3 Replication metrics, you can use the replication-related Data Protection metrics provided by S3 Storage Lens dashboards. For example, if you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

For more information about working with replication metrics in S3 Storage Lens, see [the section called “Viewing replication metrics in S3 Storage Lens dashboards”](#).

- **S3 Event Notifications** – S3 Event Notifications can notify you at the object level in instances when objects don't replicate to their destination AWS Region or when objects aren't replicated within certain thresholds. S3 Event Notifications provides the following replication event types: s3:Replication:OperationFailedReplication, s3:Replication:OperationMissedThreshold, s3:Replication:OperationReplicatedAfterThreshold, and s3:Replication:OperationNotTracked.

Amazon S3 events are available through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [the section called “Receiving replication failure events”](#).

- **Replication status values** – You can also retrieve the replication status of your objects. The replication status can help you determine the current state of an object that's being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication.

For more information about retrieving the replication status of your objects, see [the section called “Getting replication status”](#). For more information about using these values with Batch Replication, see [the section called “Filters for a Batch Replication job”](#).

Topics

- [Using S3 Replication metrics](#)
- [Viewing replication metrics in S3 Storage Lens dashboards](#)
- [Receiving replication failure events with Amazon S3 Event Notifications](#)
- [Getting replication status information](#)

Using S3 Replication metrics

S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

Note

- S3 Replication metrics are billed at the same rate as Amazon CloudWatch custom metrics. For more information, see [Amazon CloudWatch pricing](#).
- If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule.

S3 Replication metrics are turned on automatically when you enable S3 Replication Time Control (S3 RTC). You can also enable S3 Replication metrics independently of S3 RTC while [creating or editing a rule](#). S3 RTC includes other features, such as a service level agreement (SLA) and notifications for missed thresholds. For more information, see [Meeting compliance requirements with S3 Replication Time Control](#).

When S3 Replication metrics are enabled, Amazon S3 publishes the following metrics to Amazon CloudWatch. CloudWatch metrics are delivered on a best-effort basis.

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Bytes Pending Replication	The total number of bytes of objects that are pending replication for a given	This metric applies only to new objects that are replicated with S3 Cross-Reg	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
	replication rule.	ion Replication (S3 CRR) or S3 Same-Region Replication (S3 SRR).			
Replication Latency	The maximum number of seconds by which the replication destination bucket is behind the source bucket for a given replication rule.	This metric applies only to new objects that are replicated with S3 CRR or S3 SRR.	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Pending Replication	The number of operations that are pending replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and S3 Object Lock.	This metric applies only to new objects that are replicated with S3 CRR or S3 SRR.	This metric is published in the Region of the destination bucket.	No	Yes

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
Operations Failed Replication	The number of operations that failed replication for a given replication rule. This metric tracks operations related to objects, delete markers, tags, access control lists (ACLs), and Object Lock.	This metric applies both to new objects that are replicated with S3 CRR or S3 SRR and also to existing objects that are replicated with S3 Batch Replication.	This metric is published in the Region of the source bucket.	Yes	No

 **Note**

If an S3 Batch Replication job fails to run at all, metrics aren't sent

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
	<p>objects that have failed replication and their failure reasons, subscribe to the Operation FailedReplication event in Amazon S3 Event Notifications. For more information, see Receiving replication failure events with Amazon S3 Event Notifications.</p>	<p>to Amazon CloudWatch. For example, your job won't run if you don't have the necessary permissions to run an S3 Batch Replication job, or if the tags or prefix in your replicati</p>			

Metric name	Metric description	Which objects does this metric apply to?	Which Region is this metric published in?	Is this metric still published if the destination bucket is deleted?	Is this metric still published if replication doesn't occur?
		on configuration don't match.			

For information about working with these metrics in CloudWatch, see [the section called "S3 Replication metrics in CloudWatch"](#).

Enabling S3 Replication metrics

You can start using S3 Replication metrics with a new or existing replication rule. For full instructions on creating replication rules, see [Configuring replication for buckets in the same account](#). You can choose to apply your replication rule to an entire S3 bucket, or to Amazon S3 objects with a specific prefix or tag.

This topic provides instructions for enabling S3 Replication metrics in your replication configuration when the source and destination buckets are owned by the same or different AWS accounts.

To enable replication metrics by using the AWS Command Line Interface (AWS CLI), you must add a replication configuration to the source bucket with Metrics enabled. In this example configuration, objects under the prefix **Tax** are replicated to the destination bucket **amzn-s3-demo-bucket**, and metrics are generated for those objects.

```
{
  "Rules": [
    {
      "Status": "Enabled",
      "Filter": {
        "Prefix": "Tax"
      }
    }
  ]
}
```

```
        },
        "Destination": {
            "Bucket": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Metrics": {
                "Status": "Enabled"
            }
        },
        "Priority": 1
    }
],
"Role": "IAM-Role-ARN"
}
```

Viewing replication metrics

You can view S3 Replication metrics in the source general purpose bucket's **Metrics** tab in the Amazon S3 console. These Amazon CloudWatch metrics are also available in the Amazon CloudWatch console. When you enable S3 Replication metrics, Amazon CloudWatch emits metrics that you can use to track bytes pending, operations pending, and replication latency at the replication rule level.

S3 Replication metrics are turned on automatically when you enable replication with S3 Replication Time Control (S3 RTC) by using the Amazon S3 console or the Amazon S3 REST API. You can also enable S3 Replication metrics independently of S3 RTC while [creating or editing a rule](#).

If you're using S3 Replication Time Control, Amazon CloudWatch begins reporting replication metrics 15 minutes after you enable S3 RTC on the respective replication rule. For more information, see [Using S3 Replication metrics](#).

Replication metrics track the rule IDs of the replication configuration. A replication rule ID can be specific to a prefix, a tag, or a combination of both.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

Prerequisites

Create a replication rule that has S3 Replication metrics enabled. For more information, see [the section called "Enabling replication metrics"](#).

To view S3 Replication metrics through the source bucket's Metrics tab

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the source bucket that contains the objects that you want replication metrics for.
4. Choose the **Metrics** tab.
5. Under **Replication metrics**, choose the replication rules that you want to see metrics for.
6. Choose **Display charts**.

Amazon S3 displays **Replication latency**, **Bytes pending replication**, **Operations pending replication**, and **Operations failed replication** charts for the rules that you selected.

Viewing replication metrics in S3 Storage Lens dashboards

In addition to [S3 Replication metrics](#), you can use the replication-related Data Protection metrics provided by S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to protect your data](#).

S3 Storage Lens has two tiers of metrics: free metrics, and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

If you use the free metrics in S3 Storage Lens, you can see metrics such as the total number of bytes that are replicated from the source bucket or the count of replicated objects from the source bucket.

To audit your overall replication stance, you can enable advanced metrics in S3 Storage Lens. With advanced metrics in S3 Storage Lens, you can see how many replication rules you have of various types, including the count of replication rules with a replication destination that's not valid.

For a complete list of S3 Storage Lens metrics, including which replication metrics are in each tier, see the [S3 Storage Lens metrics glossary](#).

Prerequisites

Create a [live replication configuration](#) or an [S3 Batch Replication job](#).

To view replication metrics in Amazon S3 Storage Lens

1. Create an S3 Storage Lens dashboard. For step-by-step instructions, see [the section called “Using the S3 console”](#).
2. (Optional) During your dashboard setup, if you want to see all S3 Storage Lens replication metrics, select **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For a complete list of metrics, see the [S3 Storage Lens metrics glossary](#).

If you enable advanced metrics and recommendations, you can gain further insights into your replication configurations. For example, you can use S3 Storage Lens replication rule count metrics to get detailed information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions. For more information, see [the section called “Count the total number of replication rules for each bucket”](#).

3. After you've created your dashboard, open the dashboard, and choose the **Buckets** tab.
4. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
5. To filter the **Buckets** list to display only replication metrics, choose the preferences icon ).
6. Clear the toggles for all data-protection metrics until only the replication metrics remain selected.
7. (Optional) Under **Page size**, choose the number of buckets to display in the list.
8. Choose **Continue**.

Receiving replication failure events with Amazon S3 Event Notifications

If you've enabled S3 Replication metrics on your replication configuration, you can set up Amazon S3 Event Notifications to notify you when objects don't replicate to their destination AWS Region. If you've enabled S3 Replication Time Control (S3 RTC) on your replication configuration, you can also be notified when objects don't replicate within the 15-minute S3 RTC threshold for replication.

By using the following Replication event types, you can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For more information about S3 Replication metrics, see [Using S3 Replication metrics](#).

- The `s3:Replication:OperationFailedReplication` event type notifies you when an object that was eligible for replication failed to replicate.
- The `s3:Replication:OperationMissedThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.
- The `s3:Replication:OperationReplicatedAfterThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.
- The `s3:Replication:OperationNotTracked` event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

For full descriptions of all the supported replication event types, see [the section called “Supported event types for SQS, SNS, and Lambda”](#).

For a list of the failure codes captured by S3 Event Notifications, see [Amazon S3 replication failure reasons](#).

You can receive S3 Event Notifications through Amazon Simple Queue Service (Amazon SQS), Amazon Simple Notification Service (Amazon SNS), or AWS Lambda. For more information, see [the section called “Amazon S3 Event Notifications”](#).

For instructions on how to configure Amazon S3 Event Notifications, see [Enabling event notifications](#).

 **Note**

In addition to enabling event notifications, make sure that you also enable S3 Replication metrics. For more information, see [the section called “Enabling replication metrics”](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:Replication:OperationFailedReplication` event. For more information, see [the section called “Event message structure”](#).

Amazon S3 replication failure reasons

The following table lists Amazon S3 Replication failure reasons. You can view these reasons by receiving the `s3:Replication:OperationFailedReplication` event with Amazon S3 Event Notifications and then looking at the `failureReason` value.

You can also view these failure reasons in an S3 Batch Replication completion report. For more information, see [Batch Replication completion report](#).

Replication failure reason	Description
<code>AssumeRoleNotPermitted</code>	Amazon S3 can't assume the AWS Identity and Access Management (IAM) role that's specified in the replication configuration or in the Batch Operations job.
<code>DstBucketInvalidRegion</code>	The destination bucket is not in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
<code>DstBucketNotFound</code>	Amazon S3 is unable to find the destination bucket that's specified in the replication configuration.
<code>DstBucketObjectLockConfigMissing</code>	To replicate objects from a source bucket with Object Lock enabled, the destination bucket must also have Object Lock enabled. This error indicates that Object Lock might not be enabled in the destination bucket. For more information, see Object Lock considerations .
<code>DstBucketUnversioned</code>	Versioning is not enabled for the S3 destination bucket. To replicate objects with S3 Replication, enable versioning for the destination bucket.

Replication failure reason	Description
DstDelObjNotPermitted	Amazon S3 is unable to replicate delete markers to the destination bucket. The <code>s3:ReplicateDelete</code> permission might be missing for the destination bucket.
DstKmsKeyInvalidState	The AWS Key Management Service (AWS KMS) key for the destination bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .
DstKmsKeyNotFound	The AWS KMS key that's configured for the destination bucket in the replication configuration doesn't exist.
DstMultipartCompleteNotPermitted	Amazon S3 is unable to complete multipart uploads of objects in the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartInitNotPermitted	Amazon S3 is unable to initiate multipart uploads of objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstMultipartPartUploadNotPermitted	Amazon S3 is unable to upload multipart upload objects to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstObjectHardDeleted	S3 Batch Replication does not support re-replicating objects deleted with the version ID of the object from the destination bucket. This error is specific to Batch Replication.

Replication failure reason	Description
DstPutAclNotPermitted	Amazon S3 is unable to replicate object access control lists (ACLs) to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstPutLegalHoldNotPermitted	Amazon S3 is unable to put an Object Lock legal hold on the destination objects when it's replicating immutable objects. The <code>s3:PutObjectLegalHold</code> permission might be missing for the destination bucket. For more information, see Legal holds .
DstPutObjectNotPermitted	Amazon S3 is unable to replicate objects to the destination bucket. The <code>s3:ReplicateObject</code> or <code>s3:ObjectOwnerOverrideToBucketOwner</code> permissions might be missing for the destination bucket.
DstPutRetentionNotPermitted	Amazon S3 is unable to put a retention period on the destination objects when it's replicating immutable objects. The <code>s3:PutObjectRetention</code> permission might be missing for the destination bucket.
DstPutTaggingNotPermitted	Amazon S3 is unable to replicate object tags to the destination bucket. The <code>s3:ReplicateObject</code> permission might be missing for the destination bucket.
DstVersionNotFound	Amazon S3 is unable to find the required object version in the destination bucket for which metadata needs to be replicated.

Replication failure reason	Description
InitiateReplicationNotPermitted	Amazon S3 is unable to initiate replication on objects. The <code>s3:InitiateReplication</code> permission might be missing for the Batch Operations job. This error is specific to Batch Replication.
SrcBucketInvalidRegion	The source bucket isn't in the same AWS Region as specified by the Batch Operations job. This error is specific to Batch Replication.
SrcBucketNotFound	Amazon S3 is unable to find the source bucket.
SrcBucketReplicationConfigMissing	Amazon S3 couldn't find a replication configuration for the source bucket.
SrcGetAclNotPermitted	<p>Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionAcl</code> permission might be missing for the source bucket object.</p> <p>The objects in the source bucket must be owned by the bucket owner. If ACLs are enabled, then verify if Object Ownership is set to Bucket owner preferred or Object writer. If Object Ownership is set to Bucket owner preferred, then the source bucket objects must have the <code>bucket-owner-full-control</code> ACL for the bucket owner to become the object owner. The source account can take ownership of all objects in their bucket by setting Object Ownership to Bucket owner enforced and disabling ACLs.</p>

Replication failure reason	Description
SrcGetLegalHoldNotPermitted	Amazon S3 is unable to access the S3 Object Lock legal hold information.
SrcGetObjectNotPermitted	Amazon S3 is unable to access the object in the source bucket for replication. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcGetRetentionNotPermitted	Amazon S3 is unable to access the S3 Object Lock retention period information.
SrcGetTaggingNotPermitted	Amazon S3 is unable to access object tag information from the source bucket. The <code>s3:GetObjectVersionTagging</code> permission might be missing for the source bucket.
SrcHeadObjectNotPermitted	Amazon S3 is unable to retrieve object metadata from the source bucket. The <code>s3:GetObjectVersionForReplication</code> permission might be missing for the source bucket.
SrcKeyNotFound	Amazon S3 is unable to find the source object key to replicate. Source object may have been deleted before replication was complete.
SrcKmsKeyInvalidState	The AWS KMS key for the source bucket isn't in a valid state. Review and enable the required AWS KMS key. For more information about managing AWS KMS keys, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i> .

Replication failure reason	Description
SrcObjectNotEligible	Some objects aren't eligible for replication. This may be due to the object's storage class or the object tags don't match the replication configuration.
SrcObjectNotFound	Source object does not exist.
SrcReplicationNotPending	Amazon S3 has already replicated this object. This object is no longer pending replication.
SrcVersionNotFound	Amazon S3 is unable to find the source object version to replicate. Source object version may have been deleted before replication was complete.

[Troubleshooting replication](#)

Getting replication status information

Replication status can help you determine the current state of an object being replicated. The replication status of a source object will return either PENDING, COMPLETED, or FAILED. The replication status of a replica will return REPLICA.

You can also use replication status values when you're creating S3 Batch Replication jobs. For example, you can use these status values to replicate objects that have either never been replicated or that have failed replication. For more information about using these values with Batch Replication, see [the section called “Using replication status information with Batch Replication jobs”](#).

Topics

- [Replication status overview](#)

- [Replication status if replicating to multiple destination buckets](#)
- [Replication status if Amazon S3 replica modification sync is enabled](#)
- [Using replication status information with Batch Replication jobs](#)
- [Finding replication status](#)

Replication status overview

In replication, you have a source bucket on which you configure replication and one or more destination buckets where Amazon S3 replicates objects. When you request an object (by using `GetObject`) or object metadata (by using `HeadObject`) from these buckets, Amazon S3 returns the `x-amz-replication-status` header in the response:

- When you request an object from the source bucket, Amazon S3 returns the `x-amz-replication-status` header if the object in your request is eligible for replication.

For example, suppose that you specify the object prefix `TaxDocs` in your replication configuration to tell Amazon S3 to replicate only objects with the key name prefix `TaxDocs`. Any objects that you upload that have this key name prefix—for example, `TaxDocs/document1.pdf`—will be replicated. For object requests with this key name prefix, Amazon S3 returns the `x-amz-replication-status` header with one of the following values for the object's replication status: `PENDING`, `COMPLETED`, or `FAILED`.

Note

If object replication fails after you upload an object, you can't retry replication. You must upload the object again, or you must use S3 Batch Replication to replicate any failed objects. For more information about using Batch Replication, see [the section called "Replicating existing objects"](#).

Objects transition to a `FAILED` state for issues such as missing replication role permissions, AWS Key Management Service (AWS KMS) permissions, or bucket permissions. For temporary failures, such as if a bucket or Region is unavailable, replication status doesn't transition to `FAILED`, but remains `PENDING`. After the resource is back online, Amazon S3 resumes replicating those objects.

- When you request an object from a destination bucket, if the object in your request is a replica that Amazon S3 created, Amazon S3 returns the `x-amz-replication-status` header with the value `REPLICA`.

Note

Before deleting an object from a source bucket that has replication enabled, check the object's replication status to make sure that the object has been replicated.

If an S3 Lifecycle configuration is enabled on the source bucket, Amazon S3 suspends lifecycle actions until it marks the objects' status as either COMPLETED or FAILED.

Replication status if replicating to multiple destination buckets

When you replicate objects to multiple destination buckets, the `x-amz-replication-status` header acts differently. The header of the source object returns a value of COMPLETED only when replication is successful to all destinations. The header remains at the PENDING value until replication has completed for all destinations. If one or more destinations fail replication, the header returns FAILED.

Replication status if Amazon S3 replica modification sync is enabled

When your replication rules enable Amazon S3 replica modification sync, replicas can report statuses other than REPLICA. If metadata changes are in the process of replicating, the `x-amz-replication-status` header returns PENDING. If replica modification sync fails to replicate metadata, the header returns FAILED. If metadata is replicated correctly, the replicas return the header REPLICA.

Using replication status information with Batch Replication jobs

When creating a Batch Replication job, you can optionally specify additional filters, such as the object creation date and replication status, to reduce the scope of the job.

You can filter objects to replicate based on the `ObjectReplicationStatuses` value, by providing one or more of the following values:

- "NONE" – Indicates that Amazon S3 has never attempted to replicate the object before.
- "FAILED" – Indicates that Amazon S3 has attempted, but failed, to replicate the object before.
- "COMPLETED" – Indicates that Amazon S3 has successfully replicated the object before.
- "REPLICA" – Indicates that this is a replica object that Amazon S3 has replicated from another source.

For more information about using these replication status values with Batch Replication, see [the section called “Filters for a Batch Replication job”](#).

Finding replication status

To get the replication status of the objects in a bucket, you can use the Amazon S3 Inventory tool. Amazon S3 sends a CSV file to the destination bucket that you specify in the inventory configuration. You can also use Amazon Athena to query the replication status in the inventory report. For more information about Amazon S3 Inventory, see [Cataloging and analyzing your data with S3 Inventory](#).

You can also find the object replication status by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the AWS SDK.

Using the S3 console

In the Amazon S3 console, you can view the replication status for an object on the object's details page.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **General purpose buckets** list, choose the name of the replication source bucket.
4. In the **Objects** list, choose the object name. The object's details page appears.
5. On the **Properties** tab, scroll down to the **Object management overview** section. Under **Management configurations**, see the value under **Replication status**.

Using the AWS CLI

Use the AWS Command Line Interface (AWS CLI) head-object command to retrieve object metadata, as shown in the following example. Replace the *amzn-s3-demo-source-bucket1* with the name of your replication source bucket, and replace the other *user input placeholders* with your own information.

```
aws s3api head-object --bucket amzn-s3-demo-source-bucket1 --key object-key --version-id object-version-id
```

The command returns object metadata, including the **ReplicationStatus** as shown in the following example response.

```
{  
    "AcceptRanges": "bytes",  
    "ContentType": "image/jpeg",  
    "LastModified": "Mon, 23 Mar 2015 21:02:29 GMT",  
    "ContentLength": 3191,  
    "ReplicationStatus": "COMPLETED",  
    "VersionId": "jfW.HIM0fYid_9rGbSkmroXsFj3fqZ.",  
    "ETag": "\"6805f2cfc46c0f04559748bb039d69ae\"",  
    "Metadata": {  
    }  
}
```

Using the AWS SDKs

The following code fragments get your replication status by using the AWS SDK for Java and AWS SDK for .NET, respectively.

Java

```
GetObjectMetadataRequest metadataRequest = new GetObjectMetadataRequest(bucketName,  
    key);  
ObjectMetadata metadata = s3Client.getObjectMetadata(metadataRequest);  
  
System.out.println("Replication Status : " +  
    metadata.getRawMetadataValue(Headers.OBJECT_REPLICATION_STATUS));
```

.NET

```
GetObjectMetadataRequest getmetadataRequest = new GetObjectMetadataRequest  
{  
    BucketName = sourceBucket,  
    Key        = objectKey  
};  
  
GetObjectMetadataResponse getmetadataResponse =  
    client.GetObjectMetadata(getmetadataRequest);  
Console.WriteLine("Object replication status: {0}",  
    getmetadataResponse.ReplicationStatus);
```

Managing multi-Region traffic with Multi-Region Access Points

Amazon S3 Multi-Region Access Points provides a global endpoint that applications can use to fulfill requests from S3 buckets that are located in multiple AWS Regions. You can use Multi-Region Access Points to build multi-Region applications with the same architecture that's used in a single Region, and then run those applications anywhere in the world. Instead of sending requests over the congested public internet, Multi-Region Access Points provides built-in network resilience with acceleration of internet-based requests to Amazon S3. Application requests made to a Multi-Region Access Point global endpoint uses [AWS Global Accelerator](#) to automatically route over the AWS global network to the closest proximity S3 bucket with an active routing status.

If a Regional traffic disruption occurs, you can use Multi-Region Access Points failover controls to shift the S3 data request traffic between AWS Regions and redirect S3 traffic away from the disruptions within minutes. You can also test the application resiliency against a disruption to conduct application failover and perform disaster recovery simulations. If you need to connect and accelerate requests to S3 from outside of a VPC, you can simplify applications and network architecture with Amazon S3 Multi-Region Access Points. Your Multi-Region Access Points requests will be routed over the AWS global network and then back to S3 within the AWS Region, without having to traverse the public internet. As a result, you can build more highly available applications.

During your Multi-Region Access Points creation and setup, you'll specify a set of AWS Regions where you want to store data to be served through that Multi-Region Access Point. You can use the provided Multi-Region Access Points endpoint name to connect your clients. After you've established your client connections, you can select the existing or new buckets that you'd like to route the Multi-Region Access Points requests between. Then, use [S3 Cross-Region Replication \(CRR\)](#) rules to synchronize data among buckets in those Regions.

After you've set up your Multi-Region Access Point, you can then request or write data through the Multi-Region Access Points global endpoint. Amazon S3 automatically serves requests to the replicated data set from the closest available Region. Within the AWS Management Console, you're also able to view the underlying replication topology and replication metrics related to your Multi-Region Access Points requests. This gives you an even easier way to build, manage, and monitor storage for multi-Region applications. Alternatively, you can use Amazon CloudFront to automate the creation and configuration of S3 Multi-Region Access Points.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-active configuration. The graphic shows how Amazon S3 requests are automatically routed to buckets in the closest active AWS Region.

The following image is a graphical representation of an Amazon S3 Multi-Region Access Point in an active-passive configuration. The graphic shows how you can control Amazon S3 data-access traffic to fail over between active and passive AWS Regions.

To learn more about how to use Multi-Region Access Points, see [Tutorial: Getting started with Amazon S3 Multi-Region Access Points](#).

Topics

- [Creating Multi-Region Access Points](#)
- [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#)
- [Making requests through a Multi-Region Access Point](#)

Creating Multi-Region Access Points

To create a Multi-Region Access Point in Amazon S3, you do the following:

- Specify the name for the Multi-Region Access Point.
- Choose one bucket in each AWS Region that you want to serve requests for the Multi-Region Access Point.
- Configure the Amazon S3 Block Public Access settings for the Multi-Region Access Point.

You provide all of this information in a create request, which Amazon S3 processes asynchronously. Amazon S3 provides a token that you can use to monitor the status of the asynchronous creation request.

Make sure to resolve security warnings, errors, general warnings, and suggestions from AWS Identity and Access Management Access Analyzer before you save your policy. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. To learn more about validating policies using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

When you use the API, the request to create a Multi-Region Access Point is asynchronous. When you submit a request to create a Multi-Region Access Point, Amazon S3 synchronously authorizes the request. It then immediately returns a token that you can use to track the progress of the creation request. For more information about tracking asynchronous requests to create and manage Multi-Region Access Points, see [Using Multi-Region Access Points with supported API operations](#).

After you create the Multi-Region Access Point, you can create an access control policy for it. Each Multi-Region Access Point can have an associated policy. A Multi-Region Access Point policy is a resource-based policy that you can use to limit the use of the Multi-Region Access Point by resource, user, or other conditions.

 **Note**

For an application or user to be able to access an object through a Multi-Region Access Point, both of the following policies must permit the request:

- The access policy for the Multi-Region Access Point
- The access policy for the underlying bucket that contains the object

When the two policies are different, the more restrictive policy takes precedence.

To simplify permissions management for Multi-Region Access Points, you can delegate access control from the bucket to the Multi-Region Access Point. For more information, see [the section called "Multi-Region Access Point policy examples"](#).

Using a bucket with a Multi-Region Access Point doesn't change the bucket's behavior when the bucket is accessed through the existing bucket name or an Amazon Resource Name (ARN). All existing operations against the bucket continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests that are made through the Multi-Region Access Point.

You can update the policy for a Multi-Region Access Point after creating it, but you can't delete the policy. However, you can update the Multi-Region Access Point policy to deny all permissions.

Rules for naming Amazon S3 Multi-Region Access Points

When you create a Multi-Region Access Point, you give it a name, which is a string that you choose. You can't change the name of the Multi-Region Access Point after it is created. The name must be unique in your AWS account, and it must conform to the naming requirements listed in [Multi-Region Access Point restrictions and limitations](#). To help you identify the Multi-Region Access Point, use a name that is meaningful to you, to your organization, or that reflects the scenario.

You use this name when invoking Multi-Region Access Point management operations, such as `GetMultiRegionAccessPoint` and `PutMultiRegionAccessPointPolicy`. The name is not used to send requests to the Multi-Region Access Point, and it doesn't need to be exposed to clients who make requests by using the Multi-Region Access Point.

When Amazon S3 creates a Multi-Region Access Point, it automatically assigns an alias to it. This alias is a unique alphanumeric string that ends in `.mrap`. The alias is used to construct the hostname and the Amazon Resource Name (ARN) for a Multi-Region Access Point. The fully qualified name is also based on the alias for the Multi-Region Access Point.

You can't determine the name of a Multi-Region Access Point from its alias, so you can disclose an alias without risk of exposing the name, purpose, or owner of the Multi-Region Access Point. Amazon S3 selects the alias for each new Multi-Region Access Point, and the alias can't be changed. For more information about addressing a Multi-Region Access Point, see [Making requests through a Multi-Region Access Point](#).

Multi-Region Access Point aliases are unique throughout time and aren't based on the name or configuration of a Multi-Region Access Point. If you create a Multi-Region Access Point, and then delete it and create another one with the same name and configuration, the second Multi-Region Access Point will have a different alias than the first. New Multi-Region Access Points can never have the same alias as a previous Multi-Region Access Point.

Rules for choosing buckets for Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point is associated with the Regions where you want to fulfill requests. The Multi-Region Access Point must be associated with exactly one bucket in each of those Regions. You specify the name of each bucket in the request to create the Multi-Region Access Point. Buckets that support the Multi-Region Access Point can either be in the same AWS account that owns the Multi-Region Access Point, or they can be in other AWS accounts.

A single bucket can be used by multiple Multi-Region Access Points.

Important

- You can specify the buckets that are associated with a Multi-Region Access Point only at the time that you create it. After it is created, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one.

- You can't delete a bucket that is part of a Multi-Region Access Point. If you want to delete a bucket that's attached to a Multi-Region Access Point, delete the Multi-Region Access Point first.
- If you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see [Multi-Region Access Point policy examples](#).
- Not all Regions support Multi-Region Access Points. To see the list of supported Regions, see [Multi-Region Access Point restrictions and limitations](#).

You can create replication rules to synchronize data between buckets. These rules enable you to automatically copy data from source buckets to destination buckets. Having buckets connected to a Multi-Region Access Point does not affect how replication works. Configuring replication with Multi-Region Access Points is described in a later section.

Important

When you make a request to a Multi-Region Access Point, the Multi-Region Access Point isn't aware of the data contents of the buckets in the Multi-Region Access Point. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, we recommend that you configure S3 Cross-Region Replication (CRR). For more information, see [Configuring replication for use with Multi-Region Access Points](#).

Create an Amazon S3 Multi-Region Access Point

The following example demonstrates how to create a Multi-Region Access Point by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose **Create Multi-Region Access Points** to begin creating your Multi-Region Access Point.
4. On the **Multi-Region Access Point** page, supply a name for the Multi-Region Access Point in the **Multi-Region Access Point name** field.
5. Select the buckets that will be associated with this Multi-Region Access Point. You can choose buckets that are in your account, or you can choose buckets from other accounts.

 **Note**

You must add at least one bucket from either your account or other accounts. Also, be aware that Multi-Region Access Points support only one bucket per AWS Region. Therefore, you can't add two buckets from the same Region. [AWS Regions that are disabled by default](#) are not supported.

- To add a bucket that is in your account, choose **Add buckets**. A list of all the buckets in your account displays. You can search for your bucket by name, or sort the bucket names in alphabetical order.
- To add a bucket from another account, choose **Add bucket from other accounts**. Make sure that you know the exact bucket name and AWS account ID because you can't search or browse for buckets in other accounts.

 **Note**

You must enter a valid AWS account ID and bucket name. The bucket must also be in a supported Region, or you will encounter an error when you try to create your Multi-Region Access Point. For the list of Regions that support Multi-Region Access Points, see [Multi-Region Access Points restrictions and limitations](#).

6. (Optional) If you need to remove a bucket that you added, choose **Remove**.

 **Note**

You can't add or remove buckets to this Multi-Region Access Point after you've finished creating it.

- Under **Block Public Access settings for this Multi-Region Access Point**, select the Block Public Access settings that you want to apply to the Multi-Region Access Point. By default, all Block Public Access settings are enabled for new Multi-Region Access Points. We recommend that you leave all settings enabled unless you know that you have a specific need to disable any of them.

 **Note**

You can't change the Block Public Access settings for a Multi-Region Access Point after the Multi-Region Access Point has been created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

- Choose **Create Multi-Region Access Point**.

 **Important**

When you add a bucket that's owned by another account to your Multi-Region Access Point, the bucket owner must also update their bucket policy to grant access permissions to the Multi-Region Access Point. Otherwise, the Multi-Region Access Point won't be able to retrieve data from that bucket. For example policies that show how to grant such access, see [Multi-Region Access Point policy examples](#).

Using the AWS CLI

You can use the AWS CLI to create a Multi-Region Access Point. When you create the Multi-Region Access Point, you must provide all the buckets that it will support. You can't add buckets to the Multi-Region Access Point after it has been created.

The following example creates a Multi-Region Access Point with two buckets by using the AWS CLI. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-multi-region-access-point --account-id 111122223333 --details '{  
    "Name": "simple-multiregionaccesspoint-with-two-regions",  
    "PublicAccessBlock": {  
        "BlockPublicAcls": true,
```

```
        "IgnorePublicAcls": true,
        "BlockPublicPolicy": true,
        "RestrictPublicBuckets": true
    },
    "Regions": [
        { "Bucket": "amzn-s3-demo-bucket1" },
        { "Bucket": "amzn-s3-demo-bucket2" }
    ]
}' --region us-west-2
```

Blocking public access with Amazon S3 Multi-Region Access Points

Each Multi-Region Access Point has distinct settings for Amazon S3 Block Public Access. These settings operate in conjunction with the Block Public Access settings for the AWS account that owns the Multi-Region Access Point and the underlying buckets.

When Amazon S3 authorizes a request, it applies the most restrictive combination of these settings. If the Block Public Access settings for any of these resources (the Multi-Region Access Point owner account, the underlying bucket, or the bucket owner account) block access for the requested action or resource, Amazon S3 rejects the request.

We recommend that you enable all Block Public Access settings unless you have a specific need to disable any of them. By default, all Block Public Access settings are enabled for a Multi-Region Access Point. If Block Public Access is enabled, the Multi-Region Access Point can't accept internet-based requests.

Important

You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

For more information about Amazon S3 Block Public Access, see [Blocking public access to your Amazon S3 storage](#).

Viewing Amazon S3 Multi-Region Access Points configuration details

The following example demonstrates how to view Multi-Region Access Point configuration details by using the Amazon S3 console.

Using the S3 console

To create a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point for which you want to view the configuration details.
 - The **Properties** tab lists all of the buckets that are associated with your Multi-Region Access Point, the creation date, the Amazon Resource Name (ARN), and the alias. The AWS account ID column also lists any buckets owned by external accounts that are associated with your Multi-Region Access Point.
 - The **Permissions** tab lists the Block Public Access settings that are applied to the buckets associated with this Multi-Region Access Point. You can also view the Multi-Region Access Point policy for your Multi-Region Access Point, if you've created one. The **Info** alert on the **Permissions** page also lists all the buckets (in your account and other accounts) for this Multi-Region Access Point that have the **Public Access is blocked** setting enabled.
 - The **Replication and failover** tab provides a map view of the buckets that are associated with your Multi-Region Access Point and the Regions that the buckets reside in. If there are buckets from another account that you don't have permission to pull data from, the Region will be marked in red on the **Replication summary** map, indicating that it is an **AWS Region with errors getting replication status**.

 **Note**

To retrieve replication status information from a bucket in an external account, the bucket owner must grant you the `s3:GetBucketReplication` permission in their bucket policy.

This tab also provides the replication metrics, replication rules, and failover statuses for the Regions that are used with your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to view the configuration details for a Multi-Region Access Point.

The following AWS CLI example gets your current Multi-Region Access Point configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point --account-id 111122223333 --name amzn-s3-demo-bucket
```

Deleting a Multi-Region Access Point

The following procedure explains how to delete a Multi-Region Access Point by using the Amazon S3 console.

Deleting a Multi-Region Access Point does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself.

Using the S3 console

To delete a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Select the option button next to the name of your Multi-Region Access Point.
4. Choose **Delete**.
5. In the **Delete Multi-Region Access Point** dialog box, enter the name of the AWS bucket that you want to delete.

 **Note**

Make sure to enter a valid bucket name. Otherwise, the **Delete** button will be disabled.

6. Choose **Delete** to confirm deletion of your Multi-Region Access Point.

Using the AWS CLI

You can use the AWS CLI to delete a Multi-Region Access Point. This action does not delete the buckets associated with the Multi-Region Access Point, only the Multi-Region Access Point itself. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-multi-region-access-point --account-id 123456789012 --details  
Name=example-multi-region-access-point-name
```

Configuring a Multi-Region Access Point for use with AWS PrivateLink

You can use Multi-Region Access Points to route Amazon S3 request traffic between AWS Regions. Each Multi-Region Access Point global endpoint routes Amazon S3 data request traffic from multiple sources without your having to build complex networking configurations with separate endpoints. These data-request traffic sources include:

- Traffic originating in a virtual private cloud (VPC)
- Traffic from on-premises data centers traveling over AWS PrivateLink
- Traffic from the public internet

If you establish an AWS PrivateLink connection to an S3 Multi-Region Access Point, you can route S3 requests into AWS, or across multiple AWS Regions, over a private connection by using a simple network architecture and configuration. When you use AWS PrivateLink, you don't need to configure a VPC peering connection.

Topics

- [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#)
- [Removing access to a Multi-Region Access Point from a VPC endpoint](#)

Configuring a Multi-Region Access Point for use with AWS PrivateLink

AWS PrivateLink provides you with private connectivity to Amazon S3 using private IP addresses in your virtual private cloud (VPC). You can provision one or more interface endpoints inside your VPC to connect to Amazon S3 Multi-Region Access Points.

You can create **com.amazonaws.s3-global.accesspoint** endpoints for Multi-Region Access Points through the AWS Management Console, AWS CLI, or AWS SDKs. To learn more about how to

configure an interface endpoint for Multi-Region Access Point, see [Interface VPC endpoints](#) in the *VPC User Guide*.

To make requests to a Multi-Region Access Point via interface endpoints, follow these steps to configure the VPC and the Multi-Region Access Point.

To configure a Multi-Region Access Point to use with AWS PrivateLink

1. Create or have an appropriate VPC endpoint that can connect to Multi-Region Access Points. For more information about creating VPC endpoints, see [Interface VPC endpoints](#) in the *VPC User Guide*.

 **Important**

Make sure to create a **com.amazonaws.s3-global.accesspoint** endpoint. Other endpoint types cannot access Multi-Region Access Points.

After this VPC endpoint is created, all Multi-Region Access Point requests in the VPC route through this endpoint if you have private DNS enabled for the endpoint. This is enabled by default.

2. If the Multi-Region Access Point policy does not support connections from VPC endpoints, you will need to update it.
3. Verify that the individual bucket policies will allow access to the users of the Multi-Region Access Point.

Remember that Multi-Region Access Points work by routing requests to buckets, not by fulfilling requests themselves. This is important to remember because the originator of the request must have permissions to the Multi-Region Access Point and be allowed to access the individual buckets in the Multi-Region Access Point. Otherwise, the request might be routed to a bucket where the originator doesn't have permissions to fulfill the request. A Multi-Region Access Point and the buckets associated can be owned by the same or another AWS account. However, VPCs from different accounts can use a Multi-Region Access Point if the permissions are configured correctly.

Because of this, the VPC endpoint policy must allow access both to the Multi-Region Access Point and to each underlying bucket that you want to be able to fulfill requests. For example, suppose that you have a Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`. It is backed by buckets `amzn-s3-demo-bucket1` and `amzn-s3-demo-bucket2`, all owned by AWS account

123456789012. In this case, the following VPC endpoint policy would allow GetObject requests from the VPC made to `mfzwi23gnjvgw.mrap` to be fulfilled by either backing bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Read-buckets-and-MRAP-VPCE-policy",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
                "arn:aws:s3:::amzn-s3-demo-bucket2/*",  
                "arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap/object/*"  
            ]  
        }]  
    ]  
}
```

As mentioned previously, you also must make sure that the Multi-Region Access Point policy is configured to support access through a VPC endpoint. You don't need to specify the VPC endpoint that is requesting access. The following sample policy would grant access to any requester trying to use the Multi-Region Access Point for the GetObject requests.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Open-read-MRAP-policy",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": "arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap/object/*"  
        }]  
    ]  
}
```

And of course, the individual buckets would each need a policy to support access from requests submitted through VPC endpoint. The following example policy grants read access to any anonymous users, which would include requests made through the VPC endpoint.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "Public-read",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": "s3:GetObject",  
            "Resource": [  
                "arn:aws:s3:::amzn-s3-demo-bucket1",  
                "arn:aws:s3:::amzn-s3-demo-bucket2/*"]  
        }]  
    }]
```

For more information about editing a VPC endpoint policy, see [Control access to services with VPC endpoints](#) in the *VPC User Guide*.

Removing access to a Multi-Region Access Point from a VPC endpoint

If you own a Multi-Region Access Point and want to remove access to it from an interface endpoint, you must supply a new access policy for the Multi-Region Access Point that prevents access for requests coming through VPC endpoints. However, if the buckets in your Multi-Region Access Point support requests through VPC endpoints, they will continue to support these requests. If you want to prevent that support, you must also update the policies for the buckets. Supplying a new access policy to the Multi-Region Access Point prevents access only to the Multi-Region Access Point, not to the underlying buckets.

Note

You can't delete an access policy for a Multi-Region Access Point. To remove access to a Multi-Region Access Point, you must provide a new access policy with the modified access that you want.

Instead of updating the access policy for the Multi-Region Access Point, you can update the bucket policies to prevent requests through VPC endpoints. In this case, users can still access the Multi-

Region Access Point through the VPC endpoint. However, if the Multi-Region Access Point request is routed to a bucket where the bucket policy prevents access, the request will generate an error message.

Making requests through a Multi-Region Access Point

Like other resources, Amazon S3 Multi-Region Access Points have Amazon Resource Names (ARNs). You can use these ARNs to direct requests to Multi-Region Access Points by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 API. You can also use these ARNs to identify Multi-Region Access Points in access control policies. A Multi-Region Access Point ARN doesn't include or disclose the name of the Multi-Region Access Point. For more information about ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

 **Note**

The Multi-Region Access Point alias and ARN cannot be used interchangeably.

Multi-Region Access Point ARNs use the following format:

`arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`

The following are a few examples of Multi-Region Access Point ARNs:

- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap` represents the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by AWS account 123456789012.
- `arn:aws:s3:::123456789012:accesspoint/*` represents all Multi-Region Access Points under the account 123456789012. This ARN matches all Multi-Region Access Points for account 123456789012, but doesn't match any Regional Amazon S3 Access Points because the ARN doesn't include an AWS Region. In contrast, the ARN `arn:aws:s3:us-west-2:123456789012:accesspoint/*` matches all Regional Amazon S3 Access Points in the Region `us-west-2` for the account 123456789012, but doesn't match any Multi-Region Access Points.

ARNs for objects that are accessed through a Multi-Region Access Point use the following format:

`arn:aws:s3:::account_id:accesspoint/MultiRegionAccessPoint_alias//key`

As with Multi-Region Access Point ARNs, the ARNs for objects that are accessed through Multi-Region Access Points don't include an AWS Region. Here are some examples.

- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01` represents the `-01`, which is accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, which is owned by account `123456789012`.
- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//*` represents all objects that can be accessed through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.
- `arn:aws:s3:::123456789012:accesspoint/mfzwi23gnjvgw.mrap//-01/finance/*` represents all objects that can be accessed under the `-01/finance/` for the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, in account `123456789012`.

Multi-Region Access Point hostnames

You can access data in Amazon S3 through a Multi-Region Access Point by using the hostname of the Multi-Region Access Point. Requests can be directed to this hostname from the public internet. If you have configured one or more internet gateways for the Multi-Region Access Point, requests can also be directed to this hostname from a virtual private cloud (VPC). For more information about creating VPC interface endpoints to use with Multi-Region Access Points, see [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#).

To make requests through a Multi-Region Access Point from a VPC by using a VPC endpoint, you can use AWS PrivateLink. When you're making requests to a Multi-Region Access Point by using AWS PrivateLink, you cannot directly use an endpoint-specific Regional DOMAIN NAME SYSTEM (DNS) name that ends with `region.vpce.amazonaws.com`. This hostname will not have a certificate associated with it, so it cannot be used directly. You can still use the public DOMAIN NAME SYSTEM (DNS) name of the VPC endpoint as a CNAME or ALIAS target. Alternatively, you can enable private DOMAIN NAME SYSTEM (DNS) on the endpoint and use the standard Multi-Region Access Point `MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com` DOMAIN NAME SYSTEM (DNS) name, as described in this section.

When you make requests to the API for Amazon S3 data operations (for example, `GetObject`) through a Multi-Region Access Point, the hostname for the request is as follows:

`MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com`

For example, to make a `GetObject` request through the Multi-Region Access Point with the alias `mfzwi23gnjvgw.mrap`, make a request to the hostname `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. The `s3-global` portion of the hostname indicates that this hostname is not for a specific Region.

Making requests through a Multi-Region Access Point is similar to making requests through a single-Region access point. However, it's important to be aware of the following differences:

- Multi-Region Access Point ARNs don't include an AWS Region. They follow the format `arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`.
- For requests made through API operations (these requests don't require the use of an ARN), Multi-Region Access Points use a different endpoint scheme. The scheme is `MultiRegionAccessPoint_alias.accesspoint.s3-global.amazonaws.com`—for example, `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`. Note the differences compared to a single-Region access point:
 - Multi-Region Access Point hostnames use their alias, not the Multi-Region Access Point name.
 - Multi-Region Access Point hostnames don't include the owner's AWS account ID.
 - Multi-Region Access Point hostnames don't include an AWS Region.
 - Multi-Region Access Point hostnames include `s3-global.amazonaws.com` instead of `s3.amazonaws.com`.
- Multi-Region Access Point requests must be signed by using Signature Version 4A (SigV4A). When you use the AWS SDKs, the SDK automatically converts a SigV4 to SigV4A. Therefore, make sure that your [AWS SDK supports](#) SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about SigV4A, see [Signing AWS API requests](#) in the [AWS General Reference](#).

Multi-Region Access Points and Amazon S3 Transfer Acceleration

Amazon S3 Transfer Acceleration is a feature that enables fast transfer of data to buckets. Transfer Acceleration is configured on the individual bucket level. For more information about Transfer Acceleration, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Multi-Region Access Points use a similar accelerated transfer mechanism as Transfer Acceleration for sending large objects over the AWS network. Because of this, you don't need to use Transfer Acceleration when sending requests through a Multi-Region Access Point. This increased transfer performance is automatically incorporated into the Multi-Region Access Point.

Topics

- [Permissions](#)
- [Multi-Region Access Point restrictions and limitations](#)
- [Multi-Region Access Point request routing](#)
- [Amazon S3 Multi-Region Access Points failover controls](#)
- [Configuring replication for use with Multi-Region Access Points](#)
- [Using Multi-Region Access Points with supported API operations](#)
- [Monitoring and logging requests made through a Multi-Region Access Point to underlying resources](#)

Permissions

Amazon S3 Multi-Region Access Points can simplify data access for Amazon S3 buckets in multiple AWS Regions. Multi-Region Access Points are named global endpoints that you can use to perform Amazon S3 data-access object operations, such as `GetObject` and `PutObject`. Each Multi-Region Access Point can have distinct permissions and network controls for any request that is made through the global endpoint.

Each Multi-Region Access Point can also enforce a customized access policy that works in conjunction with the bucket policy that is attached to the underlying bucket. For a cross-account request to succeed, the following policies must permit the operation:

- The Multi-Region Access Point policy
- The underlying AWS Identity and Access Management (IAM) policy
- The underlying bucket policy (where the request is routed to)

 **Note**

For same account requests, only the underlying IAM policy, which grants the appropriate access, is required.

You can configure any Multi-Region Access Point policy to accept requests only from specific IAM users or groups. For an example of how to do this, see Example 2 in [the section called “Multi-Region Access Point policy examples”](#). To restrict Amazon S3 data access to a private network, you

can configure the Multi-Region Access Point policy to accept requests only from a virtual private cloud (VPC).

For example, suppose that you make a `GetObject` request through a Multi-Region Access Point by using a user called `AppDataReader` in your AWS account. To help ensure that the request won't be denied, the `AppDataReader` user must be granted the `s3:GetObject` permission by the Multi-Region Access Point and by each bucket underlying the Multi-Region Access Point. `AppDataReader` won't be able to retrieve data from any bucket that doesn't grant this permission.

Important

Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Managing public access to a Multi-Region Access Point

Multi-Region Access Points support independent Block Public Access settings for each Multi-Region Access Point. When you create a Multi-Region Access Point, you can specify the Block Public Access settings that apply to that Multi-Region Access Point.

Note

Any Block Public Access settings that are enabled under **Block Public Access settings for this account** (in your own account) or **Block Public Settings for external buckets** still apply even if the independent Block Public Access settings for your Multi-Region Access Point are disabled.

For any request that is made through a Multi-Region Access Point, Amazon S3 evaluates the Block Public Access settings for:

- The Multi-Region Access Point
- The underlying buckets (including external buckets)
- The account that owns the Multi-Region Access Point

- The account that owns the underlying buckets (including external accounts)

If any of these settings indicate that the request should be blocked, Amazon S3 rejects the request. For more information about the Amazon S3 Block Public Access feature, see [Blocking public access to your Amazon S3 storage](#).

 **Important**

By default, all Block Public Access settings are enabled for Multi-Region Access Points. You must explicitly turn off any settings that you don't want to apply to a Multi-Region Access Point.

You can't change the Block Public Access settings for a Multi-Region Access Point after it has been created.

Viewing Block Public Access settings for a Multi-Region Access Point

To view the Block Public Access settings for a Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to review.
4. Choose the **Permissions** tab.
5. Under **Block Public Access settings for this Multi-Region Access Point**, review the Block Public Access settings for your Multi-Region Access Point.

 **Note**

You can't edit the Block Public Access settings after the Multi-Region Access Point is created. Therefore, if you're going to block public access, make sure that your applications work correctly without public access before you create a Multi-Region Access Point.

Using a Multi-Region Access Point policy

The following example Multi-Region Access Point policy grants an IAM user access to list and download files from your Multi-Region Access Point. To use this example policy, replace the *user input placeholders* with your own information.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/JohnDoe"  
            },  
            "Action": [  
                "s3>ListBucket",  
                "s3GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias",  
                "arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/  
            *"  
            ]  
        }  
    ]  
}
```

To associate your Multi-Region Access Point policy with the specified Multi-Region Access Point by using the AWS Command Line Interface (AWS CLI), use the following `put-multi-region-access-point-policy` command. To use this example command, replace the *user input placeholders* with your own information. Each Multi-Region Access Point can have only one policy, so a request made to the `put-multi-region-access-point-policy` action replaces any existing policy that is associated with the specified Multi-Region Access Point.

AWS CLI

```
aws s3control put-multi-region-access-point-policy  
--account-id 111122223333  
--details { "Name": "amzn-s3-demo-bucket-MultiRegionAccessPoint",  
    "Policy": "{ \"Version\": \"2012-10-17\", \"Statement\": { \"Effect\":  
        \"Allow\", \"Principal\": { \"AWS\": \"arn:aws:iam::111122223333:root\" },  
        \"Action\": [\"s3>ListBucket\", \"s3GetObject\"], \"Resource\":  
    }
```

```
[ \"arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias",  
\"arn:aws:s3:::111122223333:accesspoint/MultiRegionAccessPoint_alias/object/*  
\" ] } }" ]
```

To query your results for the previous operation, use the following command:

AWS CLI

```
aws s3control describe-multi-region-access-point-operation  
--account-id 111122223333  
--request-token-arn requestArn
```

To retrieve your Multi-Region Access Point policy, use the following command:

AWS CLI

```
aws s3control get-multi-region-access-point-policy  
--account-id 111122223333  
--name=amzn-s3-demo-bucket-MultiRegionAccessPoint
```

Editing the Multi-Region Access Point policy

The Multi-Region Access Point policy (written in JSON) provides storage access to the Amazon S3 buckets that are used with this Multi-Region Access Point. You can allow or deny specific principals to perform various actions on your Multi-Region Access Point. When a request is routed to a bucket through the Multi-Region Access Point, both the access policies for the Multi-Region Access Point and the bucket apply. The more restrictive access policy always takes precedence.

Note

If a bucket contains objects that are owned by other accounts, the Multi-Region Access Point policy doesn't apply to the objects that are owned by other AWS accounts.

After you apply a Multi-Region Access Point policy, the policy cannot be deleted. You can either edit the policy or create a new policy that overwrites the existing one.

To edit the Multi-Region Access Point policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to edit the policy for.
4. Choose the **Permissions** tab.
5. Scroll down to the **Multi-Region Access Point policy** section. Choose **Edit** to update the policy (in JSON).
6. The **Edit Multi-Region Access Point policy** page appears. You can either enter the policy directly into the text field, or you can choose **Add statement** to select policy elements from a dropdown list.

 **Note**

The console automatically displays the Multi-Region Access Point Amazon Resource Name (ARN), which you can use in the policy. For example Multi-Region Access Point policies, see [the section called “Multi-Region Access Point policy examples”](#).

Multi-Region Access Point policy examples

Amazon S3 Multi-Region Access Points support AWS Identity and Access Management (IAM) resource policies. You can use these policies to control the use of the Multi-Region Access Point by resource, user, or other conditions. For an application or user to be able to access objects through a Multi-Region Access Point, both the Multi-Region Access Point and the underlying bucket must allow the same access.

To allow the same access to both the Multi-Region Access Point and the underlying bucket, do one of the following:

- **(Recommended)** To simplify access controls when using an Amazon S3 Multi-Region Access Point, delegate access control for the Amazon S3 bucket to the Multi-Region Access Point. For an example of how to do this, see Example 1 in this section.
- Add the same permissions contained in the Multi-Region Access Point policy to the underlying bucket policy.

Important

Delegating access control for a bucket to a Multi-Region Access Point policy doesn't change the bucket's behavior when the bucket is accessed directly through its bucket name or Amazon Resource Name (ARN). All operations made directly against the bucket will continue to work as before. Restrictions that you include in a Multi-Region Access Point policy apply only to requests made through that Multi-Region Access Point.

Example 1 – Delegating access to specific Multi-Region Access Points in your bucket policy (for the same account or cross-account)

The following example bucket policy grants full bucket access to a specific Multi-Region Access Point. This means that all access to this bucket is controlled by the policies that are attached to the Multi-Region Access Point. We recommend configuring your buckets this way for all use cases that don't require direct access to the bucket. You can use this bucket policy structure for Multi-Region Access Points in either the same account or in another account.

```
{  
    "Version": "2012-10-17",  
    "Statement" : [  
        {  
            "Effect": "Allow",  
            "Principal" : { "AWS": "*" },  
            "Action" : "*",  
            "Resource" : [ "Bucket ARN", "Bucket ARN/*"],  
            "Condition": {  
                "StringEquals" : { "s3:DataAccessPointArn" : "MultiRegionAccessPoint_ARN" }  
            }  
        ]  
    ]  
}
```

Note

If there are multiple Multi-Region Access Points that you're granting access to, make sure to list each Multi-Region Access Point.

Example 2 – Granting an account access to a Multi-Region Access Point in your Multi-Region Access Point policy

The following Multi-Region Access Point policy allows account **123456789012** permission to list and read the objects contained in the Multi-Region Access Point defined by the ***MultiRegionAccessPoint_ARN***.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/JohnDoe"  
            },  
            "Action": [  
                "s3>ListBucket",  
                "s3GetObject"  
            ],  
            "Resource": [  
                "MultiRegionAccessPoint_ARN",  
                "MultiRegionAccessPoint_ARN/object/*"  
            ]  
        }  
    ]  
}
```

Example 3 – Multi-Region Access Point policy that allows bucket listing

The following Multi-Region Access Point policy allows account **123456789012** permission to list the objects contained in the Multi-Region Access Point defined by the ***MultiRegionAccessPoint_ARN***.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/JohnDoe"  
            },  
            "Action": "s3>ListBucket",  
            "Resource": "MultiRegionAccessPoint_ARN"  
        }  
    ]  
}
```

```
        "Resource": "MultiRegionAccessPoint_ARN"
    }
]
```

Multi-Region Access Point restrictions and limitations

Multi-Region Access Points in Amazon S3 have the following restrictions and limitations.

- Multi-Region Access Point names:
 - Must be unique within a single AWS account
 - Must begin with a number or lowercase letter
 - Must be between 3 and 50 characters long
 - Can't begin or end with a hyphen (-)
 - Can't contain underscores (_), uppercase letters, or periods (.)
 - Can't be edited after they are created
- Multi-Region Access Point aliases are generated by Amazon S3 and can't be edited or reused.
- You cannot access data through a Multi-Region Access Point by using gateway endpoints. However, you can access data through a Multi-Region Access Point by using interface endpoints. To use AWS PrivateLink, you must create VPC endpoints. For more information, see [Configuring a Multi-Region Access Point for use with AWS PrivateLink](#).
- To use Multi-Region Access Points with Amazon CloudFront, you must configure the Multi-Region Access Point as a Custom Origin distribution type. For more information about various origin types, see [Using various origins with CloudFront distributions](#). For more information about using Multi-Region Access Points with Amazon CloudFront, see [Building an active-active, proximity-based application across multiple Regions](#) on the [AWS Storage Blog](#).
- Multi-Region Access Point minimum requirements:
 - Transport Layer Security (TLS) v1.2
 - Signature Version 4 (SigV4A)

Multi-Region Access Points support Signature Version 4A. This version of SigV4 allows requests to be signed for multiple AWS Regions. This feature is useful in API operations that might result in data access from one of several Regions. When using an AWS SDK, you supply your credentials, and the requests to Multi-Region Access Points will use Signature Version 4A without additional configuration. Make sure to check your [AWS SDK compatibility](#) with the

SigV4A algorithm. For more information about SigV4A, see [Signing AWS API requests](#) in the [AWS General Reference](#).

 **Note**

To use SigV4A with temporary security credentials—for example, when using AWS Identity and Access Management (IAM) roles—you can request the temporary credentials from a Regional AWS Security Token Service (AWS STS) endpoint.

If you request temporary credentials from the global AWS STS endpoint (`sts.amazonaws.com`), then you must first set the Region compatibility of session tokens for the global endpoint to be valid in all AWS Regions. For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

- Multi-Region Access Points don't support anonymous requests.
- Multi-Region Access Point limitations:
 - IPv6 is not supported.
 - Amazon S3 on Outposts buckets are not supported.
 - Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.
 - The S3 Batch Operations feature is not supported.
- Certain AWS SDKs are not supported. To confirm which AWS SDKs are supported for Multi-Region Access Points, see [Compatibility with AWS SDKs](#).
- The service quotas for Multi-Region Access Points are as follows:
 - There is a maximum of 100 Multi-Region Access Points per account.
 - There is a limit of 17 Regions for a single Multi-Region Access Point.
- After you create a Multi-Region Access Point, you can't add, modify, or remove buckets from the Multi-Region Access Point configuration. To change the buckets, you must delete the entire Multi-Region Access Point and create a new one. If a cross-account bucket in your Multi-Region Access Point is deleted, the only way to reconnect this bucket is to recreate the bucket, using the same name and Region in that account.
- Underlying buckets (in the same account) that are used in a Multi-Region Access Point can be deleted only after a Multi-Region Access Point is deleted.
- All control plane requests to create or maintain Multi-Region Access Points must be routed to the US West (Oregon) Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified.

- For the Multi-Region Access Point failover control plane, requests must be routed to one of these five supported Regions:
 - US East (N. Virginia)
 - US West (Oregon)
 - Asia Pacific (Sydney)
 - Asia Pacific (Tokyo)
 - Europe (Ireland)
- Your Multi-Region Access Point only supports buckets in the following AWS Regions:
 - US East (N. Virginia)
 - US East (Ohio)
 - US West (N. California)
 - US West (Oregon)
 - Asia Pacific (Mumbai)
 - Asia Pacific (Osaka)
 - Asia Pacific (Seoul)
 - Asia Pacific (Singapore)
 - Asia Pacific (Sydney)
 - Asia Pacific (Tokyo)
 - Canada (Central)
 - Europe (Frankfurt)
 - Europe (Ireland)
 - Europe (London)
 - Europe (Paris)
 - Europe (Stockholm)
 - South America (São Paulo)

Multi-Region Access Point request routing

When you make a request through a Multi-Region Access Point, Amazon S3 determines which of

the buckets that are associated with the Multi-Region Access Point is closest to you. Amazon S3

Using Multi-Region Access Points API Version 2006-03-01 1858

then directs the request to that bucket, regardless of the AWS Region it is located in.

After the Multi-Region Access Point routes the request to the closest-proximity bucket, Amazon S3 processes the request as if you made it directly to that bucket. Multi-Region Access Points aren't aware of the data contents of an Amazon S3 bucket. Therefore, the bucket that gets the request might not contain the requested data. To create consistent datasets in the Amazon S3 buckets that are associated with a Multi-Region Access Point, you can configure S3 Cross-Region Replication (CRR). Then any bucket can fulfill the request successfully.

Amazon S3 directs Multi-Region Access Point requests according to the following rules:

- Amazon S3 optimizes requests to be fulfilled according to proximity. It looks at the buckets supported by the Multi-Region Access Point and relays the request to the bucket that has the closest proximity.
- If the request specifies an existing resource (for example, `GetObject`), Amazon S3 does *not* consider the name of the object when fulfilling the request. This means that even if an object exists in one bucket in the Multi-Region Access Point, your request can be routed to a bucket that doesn't contain the object. This situation will result in a 404 error message being returned to the client.

To avoid 404 errors, we recommend that you configure S3 Cross-Region Replication (CRR) for your buckets. Replication helps resolve the potential issue when the object that you want is in a bucket in the Multi-Region Access Point, but it's not located in the specific bucket that your request was routed to. For more information about configuring replication, see [Configuring replication for use with Multi-Region Access Points](#).

To ensure that your requests are fulfilled by using the specific objects that you want, we also recommend that you turn on bucket versioning and include version IDs in your requests. This approach helps ensure that you have the correct version of the object that you are looking for. Versioning-enabled buckets can also help you recover objects from accidental overwrite. For more information, see [Using S3 Versioning in S3 buckets](#).

- If the request is to create a resource (for example, `PutObject` or `CreateMultipartUpload`), Amazon S3 fulfills the request by using the closest-proximity bucket. For example, consider a video company that wants to support video uploads from anywhere in the world. When a user makes a PUT request to the Multi-Region Access Point, the object is put into the bucket with the closest proximity. To then make that uploaded video available to others around the world for download with the lowest latency, you can use CRR with bidirectional (two-way) replication. Using CRR with two-way replication keeps the contents of all the buckets that are associated with the Multi-Region Access Point synchronized. For more information about using replication

with Multi-Region Access Points, see [Configuring replication for use with Multi-Region Access Points](#).

Amazon S3 Multi-Region Access Points failover controls

With Amazon S3 Multi-Region Access Point failover controls, you can maintain business continuity during Regional traffic disruptions, while also giving your applications a multi-Region architecture to fulfill compliance and redundancy needs. If your Regional traffic gets disrupted, you can use Multi-Region Access Point failover controls to select which AWS Regions behind an Amazon S3 Multi-Region Access Point will process data-access and storage requests.

To support failover, you can set up your Multi-Region Access Point in an active-passive configuration, with traffic flowing to the active Region during normal conditions, and a passive Region on standby for failover.

For example, to perform failover to an AWS Region of your choice, you shift traffic from your primary (active) Region to your secondary (passive) Region. In an active-passive configuration like this, one bucket is active and accepting traffic, while the other bucket is passive and not accepting traffic. The passive bucket is used for disaster recovery. When you initiate failover, all traffic (such as GET or PUT requests) is directed to the bucket in the active state (in one Region) and away from the bucket in the passive state (in another Region).

If you have S3 Cross-Region Replication (CRR) enabled with two-way replication rules, you can keep your buckets synchronized during a failover. In addition, if you have CRR enabled in an active-active configuration, Amazon S3 Multi-Region Access Points can also fetch data from the bucket location of closest proximity, which improves application performance.

AWS Region support

With Amazon S3 Multi-Region Access Points failover controls, your S3 buckets can be in any of the [17 Regions](#) where Multi-Region Access Points are supported. You can initiate failover across any two Regions at one time.

Note

Although failover is initiated between only two Regions at one time, you can separately update the routing statuses for multiple Regions at the same time in your Multi-Region Access Point.

The following topics demonstrate how to use and manage Amazon S3 Multi-Region Access Point failover controls.

Topics

- [Amazon S3 Multi-Region Access Points routing states](#)
- [Using Amazon S3 Multi-Region Access Point failover controls](#)
- [Amazon S3 Multi-Region Access Point failover controls errors](#)

Amazon S3 Multi-Region Access Points routing states

Your Amazon S3 Multi-Region Access Points failover configuration determines the routing status of the AWS Regions that are used with the Multi-Region Access Point. You can configure your Amazon S3 Multi-Region Access Point to be in an active-active state or active-passive state.

- **Active-active** – In an active-active configuration, all requests are automatically sent to the closest proximity AWS Region in your Multi-Region Access Point. After the Multi-Region Access Point has been configured to be in an active-active state, all Regions can receive traffic. If traffic disruption occurs in an active-active configuration, network traffic will automatically be redirected to one of the active Regions.
- **Active-passive** – In an active-passive configuration, the active Regions in your Multi-Region Access Point receive traffic and the passive ones do not. If you intend to use S3 failover controls to initiate failover in a disaster situation, set up your Multi-Region Access Points in an active-passive configuration while you're testing and performing disaster-recovery planning.

Using Amazon S3 Multi-Region Access Point failover controls

This section explains how to manage and use your Amazon S3 Multi-Region Access Points failover controls by using the AWS Management Console.

There are two failover controls in the **Failover configuration** section on your Multi-Region Access Point details page in the AWS Management Console: **Edit routing status** and **Failover**. You can use these controls as follows:

- **Edit routing status** – You can manually edit the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status**. You can use **Edit routing status** for the following purposes:
 - To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point

- To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
- To manually fail over your Regions
- To manually switch traffic between Regions
- **Failover** – When you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

Editing the routing status of the Regions in your Multi-Region Access Point

You can manually update the routing statuses of up to 17 AWS Regions in a single request for your Multi-Region Access Point by choosing **Edit routing status** in the **Failover configuration** section on your Multi-Region Access Point details page. However, when you initiate failover by choosing **Failover**, you are only updating the routing statuses of two Regions that are already configured to be in an active-passive state. During a failover that you initiated by choosing **Failover**, the routing statuses between the two Regions are automatically switched.

You can use **Edit routing status** (as described in the following procedure) for the following purposes:

- To set or edit the routing statuses of one or more Regions in your Multi-Region Access Point
- To create a failover configuration for your Multi-Region Access Point by configuring two Regions to be in an active-passive state
- To manually fail over your Regions
- To manually switch traffic between Regions

Using the S3 console

To update the routing status of the Regions in your Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to update.

5. Choose the **Replication and failover** tab.
6. Select one or more Regions that you want to edit the routing status of.

 **Note**

To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

7. Choose **Edit routing status**.
8. In the dialog box that appears, select **Active** or **Passive** for the **Routing status** for each Region.

An active state allows traffic to be routed to the Region. A passive state stops any traffic from being directed to the Region.

If you are creating a failover configuration for your Multi-Region Access Point or initiating failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point.

9. Choose **Save routing status**. It takes about 2 minutes for traffic to be redirected.

After you submit the routing status of the AWS Regions for your Multi-Region Access Point, you can verify your routing status changes. To verify these changes, go to Amazon CloudWatch at <https://console.aws.amazon.com/cloudwatch/> to monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Using the AWS CLI

 **Note**

You can run Multi-Region Access Point AWS CLI routing commands against any of these five Regions:

- ap-southeast-2
- ap-northeast-1
- us-east-1
- us-west-2

- eu-west-1

The following example command updates your current Multi-Region Access Point route configuration. To update the active or passive status of a bucket, set the TrafficDialPercentage value to 100 for active and to 0 for passive. In this example, *amzn-s3-demo-bucket1* is set to active, and *amzn-s3-demo-bucket2* is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 123456789012
--mrap MultiRegionAccessPoint_ARN
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
          Bucket=amzn-s3-demo-bucket2
          ,TrafficDialPercentage=0
```

The following example command gets your updated Multi-Region Access Point routing configuration. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 123456789012
--mrap MultiRegionAccessPoint_ARN
```

Initiating failover

When you initiate failover by choosing **Failover** in the **Failover configuration** section on your Multi-Region Access Point details page, Amazon S3 request traffic automatically gets shifted to an alternate AWS Region. The failover process is completed within 2 minutes.

You can initiate a failover across any two AWS Regions at one time (of the [17 Regions](#) where Multi-Region Access Points are supported). Failover events are then logged in AWS CloudTrail. Upon failover completion, you can monitor Amazon S3 traffic and any traffic routing updates to the new active Region in Amazon CloudWatch.

Important

To keep all metadata and objects in sync across buckets during data replication, we recommend that you create two-way replication rules and enable replica modification sync before configuring your failover controls.

Two-way replication rules help ensure that when data is written to the Amazon S3 bucket that traffic fails over to, that data is then replicated back to the source bucket. Replica modification sync helps ensure that object metadata is also synchronized between buckets during two-way replication.

For more information about configuring replication to support failover, see [the section called “Bucket replication”](#).

To initiate failover between replicated buckets

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to use to initiate failover.
5. Choose the **Replication and failover** tab.
6. Scroll down to the **Failover configuration** section and select two AWS Regions.

Note

To initiate failover, at least one AWS Region must be designated as **Active** and one Region must be designated as **Passive** in your Multi-Region Access Point. An active state allows traffic to be directed to a Region. A passive state stops any traffic from being directed to the Region.

7. Choose **Failover**.
8. In the dialog box, choose **Failover** again to initiate the failover process. During this process, the routing statuses of the two Regions are automatically switched. All new traffic is directed to the Region that becomes active, and traffic stops being directed to the Region that becomes passive. It takes about 2 minutes for traffic to be redirected.

After you initiate the failover process, you can verify your traffic changes. To verify these changes, go to Amazon CloudWatch at <https://console.aws.amazon.com/cloudwatch/> to

monitor the shift of your Amazon S3 data-request traffic (for example, GET and PUT requests) between active and passive Regions. Any existing connections will not be terminated during failover. Existing connections will continue until they reach a success or failure status.

Viewing your Amazon S3 Multi-Region Access Point routing controls

Using the S3 console

To view the routing controls for your Amazon S3 Multi-Region Access Point

1. Sign in to the AWS Management Console.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. In the left navigation pane, choose **Multi-Region Access Points**.
4. Choose the Multi-Region Access Point that you want to review.
5. Choose the **Replication and failover** tab. This page displays the routing configuration details and summary for your Multi-Region Access Point, associated replication rules, and replication metrics. You can see the routing status of your Regions in the **Failover configuration** section.

Using the AWS CLI

The following example AWS CLI command gets your current Multi-Region Access Point route configuration for the specified Region. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes  
--region eu-west-1  
--account-id 123456789012  
--mrap MultiRegionAccessPoint_ARN
```

Note

This command can only be executed against these five Regions:

- ap-southeast-2
- ap-northeast-1
- us-east-1

- us-west-2
- eu-west-1

Amazon S3 Multi-Region Access Point failover controls errors

When you update the failover configuration for your Multi-Region Access Point, you might encounter one of these errors:

- HTTP 400 Bad Request: This error can occur if you enter an invalid Multi-Region Access Point ARN while updating your failover configuration. You can confirm your Multi-Region Access Point ARN by reviewing your Multi-Region Access Point policy. To review or update your Multi-Region Access Point policy, see [Editing the Multi-Region Access Point policy](#). This error can also occur if you use an empty string or a random string while updating your Amazon S3 Multi-Region Access Point failover controls. Make sure to use the Multi-Region Access Point ARN format:

`arn:aws:s3:::account-id:accesspoint/MultiRegionAccessPoint_alias`

- HTTP 503 Slow Down: This error occurs if you send too many requests in a short period of time. Rejected requests will result in an error.
- HTTP 409 Conflict: This error occurs when two or more concurrent route configuration update requests are targeting a single Multi-Region Access Point. The first request succeeds, but any other requests fail with an error.
- HTTP 405 Method Not Allowed: This error occurs when you've selected a Multi-Region Access Point with only one AWS Region when initiating failover. You must select two Regions before you can initiate failover. Otherwise, an error is returned.

Configuring replication for use with Multi-Region Access Points

When you make a request to a Multi-Region Access Point endpoint, Amazon S3 automatically routes the request to the bucket that is closest to you. Amazon S3 doesn't consider the contents of the request when making this decision. If you make a request to GET an object, your request might be routed to a bucket that doesn't have a copy of this object. If that happens, you receive an HTTP status code 404 (Not Found) error. For more information about Multi-Region Access Point request routing, see [the section called "Request routing"](#).

If you want the Multi-Region Access Point to be able to retrieve the object regardless of which bucket receives the request, you must configure Amazon S3 Cross-Region Replication (CRR).

For example, consider a Multi-Region Access Point with three buckets:

- A bucket named my-bucket-usw2 in the Region us-west-2 that contains the object my-image.jpg
- A bucket named my-bucket-aps1 in the Region ap-south-1 that contains the object my-image.jpg
- A bucket named my-bucket-euc1 in the Region eu-central-1 that doesn't contain the object my-image.jpg

In this situation, if you make a GetObject request for the object my-image.jpg, the success of that request depends upon which bucket receives your request. Because Amazon S3 doesn't consider the contents of the request, it might route your GetObject request to the my-bucket-euc1 bucket if that bucket responds of closest proximity. Even though your object is in a bucket in the Multi-Region Access Point, you will get an HTTP 404 Not Found error because the individual bucket that received your request didn't have the object.

Enabling Cross-Region Replication (CRR) helps avoid this result. With appropriate replication rules, the my-image.jpg object is copied over to the my-bucket-euc1 bucket. Therefore, if Amazon S3 routes your request to that bucket, you can now retrieve the object.

Replication works as normal with buckets that are assigned to a Multi-Region Access Point. Amazon S3 doesn't perform any special replication handling with buckets that are in Multi-Region Access Points. For more information about configuring replication in your buckets, see [Setting up live replication overview](#).

Recommendations for using replication with Multi-Region Access Points

For the best replication performance when working with Multi-Region Access Points, we recommend the following:

- Configure S3 Replication Time Control (S3 RTC). To replicate your data across different Regions within a predictable time frame, you can use S3 RTC. S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called "Using S3 Replication Time Control"](#). There are additional charges for S3 RTC. For information, see [Amazon S3 pricing](#).
- Use two-way (bidirectional) replication to support keeping buckets synchronized when buckets are updated through the Multi-Region Access Point. For more information, see [the section called "Create two-way replication rules for your Multi-Region Access Point"](#).

- Create cross-account Multi-Region Access Points to replicate data to buckets in separate AWS accounts. This approach provides account-level separation, so that data can be accessed from and replicated across different accounts in different Regions other than the source bucket. Setting up cross-account Multi-Region Access Points comes at no additional cost. If you're a bucket owner but don't own the Multi-Region Access Point, you pay only for data transfer and request costs. Multi-Region Access Point owners pay for data routing and internet-acceleration costs. For more information, see [Amazon S3 pricing](#).
- Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see [Enabling replica modification sync](#).
- Enable Amazon CloudWatch metrics to [monitor replication events](#). CloudWatch metrics fees apply. For more information, see [Amazon CloudWatch pricing](#).

Topics

- [Create one-way replication rules for your Multi-Region Access Point](#)
- [Create two-way replication rules for your Multi-Region Access Point](#)
- [View the replication rules for your Multi-Region Access Point](#)

Create one-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A one-way replication rule helps ensure that data is fully replicated from a source bucket in one AWS Region to a destination bucket in another Region. When one-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the destination bucket (DOC-EXAMPLE-BUCKET-2) is created. Like all replication rules, you can apply the one-way replication rule to the entire Amazon S3 bucket or to a subset of objects that are filtered by a prefix or object tags.

Important

We recommend using one-way replication if your users will only be consuming the objects in your destination buckets. If your users will be uploading or modifying the objects in your destination buckets, use two-way replication to keep all of your buckets in sync. We also recommend two-way replication if you plan to use your Multi-Region Access Point for failover. To set up two-way replication, see [the section called “Create two-way replication rules for your Multi-Region Access Point”](#).

To create a one-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**. Make sure that you have sufficient permissions to create the replication rule, or versioning will be disabled.

 **Note**

You can create replication rules only for buckets in your own account. To create replication rules for external buckets, the bucket owners must create the replication rules for those buckets.

6. On the **Create replication rules** page, choose the **Replicate objects from one or more source buckets to one or more destination buckets** template.

 **Important**

When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.

To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, SDKs, or REST API. For more information, see [Replication configuration file elements](#).

7. In the **Source and destination** section, under **Source buckets**, select one or more buckets that you want to replicate objects from. All buckets (source and destination) that are chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see [Using versioning in Amazon S3 buckets](#).

Under **Destination buckets**, select one or more buckets that you want to replicate objects to.

Note

Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see [Creating an IAM role](#).

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

Note

You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

- To replicate the whole bucket, choose **Apply to all objects in the bucket**.
- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

You can filter your objects by using a prefix, object tags, or a combination of both.

- To limit replication to all objects that have names that begin with the same string (for example pictures), enter a prefix in the **Prefix** box.

If you enter a prefix that is the name of a folder, you must use a delimiter such as a / (forward slash) to indicate its level of hierarchy (for example, pictures/). For more information about prefixes, see [Organizing objects using prefixes](#).

- To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see [Categorizing your storage using tags](#).

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

Note

We recommend that you apply the following options:

- **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called “Using S3 Replication Time Control”](#).
- **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.
- **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see [Replicating delete markers between buckets](#).

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see [Amazon S3 Pricing](#) and [Amazon CloudWatch pricing](#).

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new one-way replication rule.

Create two-way replication rules for your Multi-Region Access Point

Replication rules enable automatic and asynchronous copying of objects across buckets. A two-way replication rule (also known as a bidirectional replication rule) ensures that data is fully synchronized between two or more buckets in different AWS Regions. When two-way replication is set up, a replication rule from the source bucket (DOC-EXAMPLE-BUCKET-1) to the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) is created. Then, a second replication rule from the bucket containing the replicas (DOC-EXAMPLE-BUCKET-2) to the source bucket (DOC-EXAMPLE-BUCKET-1) is created.

Like all replication rules, you can apply the two-way replication rule to the entire Amazon S3 bucket or to a subset of objects filtered by a prefix or object tags. You can also keep metadata changes to your objects in sync by [enabling replica modification sync](#) for each replication rule. You can enable replica modification sync through the Amazon S3 console, the AWS CLI, the AWS SDKs, the Amazon S3 REST API, or AWS CloudFormation.

To monitor the replication progress of objects and object metadata in Amazon CloudWatch, enable S3 Replication metrics and notifications. For more information, see [Monitoring progress with replication metrics and Amazon S3 event notifications](#).

To create a two-way replication rule for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of the Multi-Region Access Point that you want to update.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section, and then choose **Create replication rules**.
6. On the **Create replication rules** page, choose the **Replicate objects among all specified buckets** template. The **Replicate objects among all specified buckets** template sets up two-way replication (with failover capabilities) for your buckets.

Important

When you create replication rules by using this template, they replace any existing replication rules that are already assigned to the bucket.

To add to or modify any existing replication rules instead of replacing them, go to each bucket's **Management** tab in the console, and then edit the rules in the **Replication rules** section. You can also add to or modify existing replication rules by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see [Replication configuration file elements](#).

7. In the **Buckets** section, select at least two buckets that you want to replicate objects from. All buckets chosen for replication must have S3 Versioning enabled, and each bucket must reside in a different AWS Region. For more information about S3 Versioning, see [Using versioning in Amazon S3 buckets](#).

Note

Make sure that you have the required read and replicate permissions to establish replication, or you will encounter errors. For more information, see [Creating an IAM role](#).

8. In the **Replication rule configuration** section, choose whether the replication rule will be **Enabled** or **Disabled** when it's created.

 **Note**

You can't enter a name in the **Replication rule name** box. Replication rule names are generated based on your configuration when you create the replication rule.

9. In the **Scope** section, choose the appropriate scope for your replication.

- To replicate the whole bucket, choose **Apply to all objects in the bucket**.
- To replicate a subset of the objects in the bucket, choose **Limit the scope of this rule using one or more filters**.

You can filter your objects by using a prefix, object tags, or a combination of both.

- To limit replication to all objects that have names that begin with the same string (for example pictures), enter a prefix in the **Prefix** box.

If you enter a prefix that is the name of a folder, you must use a / (forward slash) as the last character (for example, pictures/).

- To replicate all objects that have one or more object tags, choose **Add tag** and enter the key-value pair in the boxes. To add another tag, repeat the procedure. For more information about object tags, see [Categorizing your storage using tags](#).

10. Scroll down to the **Additional replication options** section, and select the replication options that you want to apply.

 **Note**

We recommend that you apply the following options, especially if you intend to configure your Multi-Region Access Point to support failover:

- **Replication time control (RTC)** – To replicate your data across different Regions within a predictable time frame, you can use S3 Replication Time Control (S3 RTC). S3 RTC replicates 99.99 percent of new objects stored in Amazon S3 within 15 minutes (backed by a service-level agreement). For more information, see [the section called "Using S3 Replication Time Control"](#).
- **Replication metrics and notifications** – Enable Amazon CloudWatch metrics to monitor replication events.

- **Delete marker replication** – Delete markers created by S3 delete operations will be replicated. Delete markers created by lifecycle rules are not replicated. For more information, see [Replicating delete markers between buckets](#).
- **Replica modification sync** – Enable replica modification sync for each replication rule to also keep metadata changes to your objects in sync. For more information, see [Enabling replica modification sync](#).

There are additional charges for S3 RTC and CloudWatch replication metrics and notifications. For more information, see [Amazon S3 Pricing](#) and [Amazon CloudWatch pricing](#).

11. If you're writing a new replication rule that replaces an existing one, select **I acknowledge that by choosing Create replication rules, these existing replication rules will be overwritten**.
12. Choose **Create replication rules** to create and save your new two-way replication rules.

View the replication rules for your Multi-Region Access Point

With Multi-Region Access Points, you can either set up one-way replication rules or two-way (bidirectional) replication rules. For information about how to manage your replication rules, see [Managing replication rules by using the Amazon S3 console](#).

To view the replication rules for your Multi-Region Access Point

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Multi-Region Access Points**.
3. Choose the name of your Multi-Region Access Point.
4. Choose the **Replication and failover** tab.
5. Scroll down to the **Replication rules** section. This section lists all of the replication rules that have been created for your Multi-Region Access Point.

Note

If you've added a bucket from another account to this Multi-Region Access Point, you must have the `s3:GetBucketReplication` permission from the bucket owner to view the replication rules for that bucket.

Using Multi-Region Access Points with supported API operations

Amazon S3 provides a set of operations to manage Multi-Region Access Points. Amazon S3 processes some of these operations synchronously and some asynchronously. When you invoke an asynchronous operation, Amazon S3 first synchronously authorizes the requested operation. If authorization is successful, Amazon S3 returns a token that you can use to track the progress and results of the requested operation.

Note

Requests that are made through the Amazon S3 console are always synchronous. The console waits until the request is completed before allowing you to submit another request.

You can view the current status and results of asynchronous operations by using the console, or you can use `DescribeMultiRegionAccessPointOperation` in the AWS CLI, AWS SDKs, or REST API. Amazon S3 provides a tracking token in the response to an asynchronous operation. You include that tracking token as an argument to `DescribeMultiRegionAccessPointOperation`. When you include the tracking token, Amazon S3 then returns the current status and results of the specified operation, including any errors or relevant resource information. Amazon S3 performs `DescribeMultiRegionAccessPointOperation` operations synchronously.

All control plane requests to create or maintain Multi-Region Access Points must be routed to the US West (Oregon) Region. For Multi-Region Access Point data plane requests, Regions don't need to be specified. For the Multi-Region Access Point failover control plane, the request must be routed to one of the five supported Regions. For more information about Multi-Region Access Point supported Regions, see [Multi-Region Access Point restrictions and limitations](#).

In addition, you must grant the `s3>ListAllMyBuckets` permission to the user, role, or other AWS Identity and Access Management (IAM) entity that makes a request to manage a Multi-Region Access Point.

The following examples demonstrate how to use Multi-Region Access Points with compatible operations in Amazon S3.

Topics

- [Multi-Region Access Point compatibility with AWS services and AWS SDKs](#)
- [Multi-Region Access Point compatibility with S3 operations](#)
- [View your Multi-Region Access Point routing configuration](#)
- [Update your underlying Amazon S3 bucket policy](#)
- [Update a Multi-Region Access Point route configuration](#)
- [Add an object to a bucket in your Multi-Region Access Point](#)
- [Retrieve objects from your Multi-Region Access Point](#)
- [List objects that are stored in a bucket underlying your Multi-Region Access Point](#)
- [Use a presigned URL with Multi-Region Access Points](#)
- [Use a bucket that's configured with Requester Pays with Multi-Region Access Points](#)

Multi-Region Access Point compatibility with AWS services and AWS SDKs

To use a Multi-Region Access Point with applications that require an Amazon S3 bucket name, use the Amazon Resource Name (ARN) of the Multi-Region Access Point when making requests by using an AWS SDK. To check which AWS SDKs are compatible with Multi-Region Access Points, see [Compatibility with AWS SDKs](#).

Multi-Region Access Point compatibility with S3 operations

You can use the following Amazon S3 data plane API operations to perform actions on objects in buckets that are associated with your Multi-Region Access Point. The following S3 operations can accept Multi-Region Access Point ARNs:

- [AbortMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [CreateMultipartUpload](#)

- [DeleteObject](#)
- [DeleteObjectTagging](#)
- [GetObject](#)
- [GetObjectAcl](#)
- [GetObjectLegalHold](#)
- [GetObjectRetention](#)
- [GetObjectTagging](#)
- [HeadObject](#)
- [ListMultipartUploads](#)
- [ListObjectsV2](#)
- [ListParts](#)
- [PutObject](#)
- [PutObjectAcl](#)
- [PutObjectLegalHold](#)
- [PutObjectRetention](#)
- [PutObjectTagging](#)
- [RestoreObject](#)
- [UploadPart](#)

 **Note**

Multi-Region Access Points supports copy operations using Multi-Region Access Points only as a destination when using the Multi-Region Access Point ARN.

You can use the following Amazon S3 control plane operations to create and manage your Multi-Region Access Points:

- [CreateMultiRegionAccessPoint](#)
- [DescribeMultiRegionAccessPointOperation](#)
- [GetMultiRegionAccessPoint](#)
- [GetMultiRegionAccessPointPolicy](#)

- [GetMultiRegionAccessPointPolicyStatus](#)
- [GetMultiRegionAccessPointRoutes](#)
- [ListMultiRegionAccessPoints](#)
- [PutMultiRegionAccessPointPolicy](#)
- [SubmitMultiRegionAccessPointRoutes](#)

View your Multi-Region Access Point routing configuration

AWS CLI

The following example command retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-multi-region-access-point-routes
--region eu-west-1
--account-id 111122223333
--mrapi arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap
```

SDK for Java

The following SDK for Java code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_EAST_1)
    .credentialsProvider(credentialsProvider)
    .build();

GetMultiRegionAccessPointRoutesRequest request =
    GetMultiRegionAccessPointRoutesRequest.builder()
        .accountId("111122223333")
        .mrapi("arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap")
        .build();

GetMultiRegionAccessPointRoutesResponse response =
    s3ControlClient.getMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'us-east-1'

const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new GetMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap',
      })
    )
    console.log('Success', data)
    return data
  } catch (err) {
    console.log('Error', err)
  }
}

run()
```

SDK for Python

The following SDK for Python code retrieves your Multi-Region Access Point route configuration so that you can see the current routing statuses for your buckets. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.get_multi_region_access_point_routes(
    AccountId=111122223333,
    Mrap=arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap)['Routes']
```

Update your underlying Amazon S3 bucket policy

To grant proper access, you must also update the underlying Amazon S3 bucket policy. The following examples delegate access control to the Multi-Region Access Point policy. After you delegate access control to the Multi-Region Access Point policy, the bucket policy is no longer used for access control when requests are made through the Multi-Region Access Point.

Here's an example bucket policy that delegates access control to the Multi-Region Access Point policy. To use this example bucket policy, replace the *user input placeholders* with your own information. To apply this policy through the AWS CLI put-bucket-policy command, as shown in the next example, save the policy in a file, for example, policy.json.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Principal": { "AWS": "*" },  
            "Effect": "Allow",  
            "Action": ["s3:*"],  
            "Resource": ["arn:aws:s3:::111122223333/*", "arn:aws:s3:::amzn-s3-demo-bucket"],  
            "Condition": {  
                "StringEquals": {  
                    "s3:DataAccessPointAccount": "44445556666"  
                }  
            }  
        }  
    ]  
}
```

The following put-bucket-policy example command associates the updated S3 bucket policy with your S3 bucket:

```
aws s3api put-bucket-policy  
--bucket amzn-s3-demo-bucket  
--policy file:///tmp/policy.json
```

Update a Multi-Region Access Point route configuration

The following example command updates the Multi-Region Access Point route configuration. Multi-Region Access Point route commands can be run against the following five Regions:

- ap-southeast-2
- ap-northeast-1

- us-east-1
- us-west-2
- eu-west-1

In a Multi-Region Access Point routing configuration, you can set buckets to an active or passive routing status. Active buckets receive traffic, whereas passive buckets do not. You can set a bucket's routing status by setting the `TrafficDialPercentage` value for the bucket to 100 for active or 0 for passive.

AWS CLI

The following example command updates your Multi-Region Access Point routing configuration. In this example, `amzn-s3-demo-bucket1` is set to active status and `amzn-s3-demo-bucket2` is set to passive. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control submit-multi-region-access-point-routes
--region ap-southeast-2
--account-id 111122223333
--mraps arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap
--route-updates Bucket=amzn-s3-demo-bucket1,TrafficDialPercentage=100
Bucket=amzn-s3-demo-bucket2,TrafficDialPercentage=0
```

SDK for Java

The following SDK for Java code updates your Multi-Region Access Point routing configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.ap-southeast-2)
    .credentialsProvider(credentialsProvider)
    .build();

SubmitMultiRegionAccessPointRoutesRequest request =
    SubmitMultiRegionAccessPointRoutesRequest.builder()
        .accountId("111122223333")
        .mraps("arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap")
        .routeUpdates(
            MultiRegionAccessPointRoute.builder()
```

```
.region("eu-west-1")
.trafficDialPercentage(100)
.build(),
MultiRegionAccessPointRoute.builder()
.region("ca-central-1")
.bucket("111122223333")
.trafficDialPercentage(0)
.build()
)
.build();

SubmitMultiRegionAccessPointRoutesResponse response =
s3ControlClient.submitMultiRegionAccessPointRoutes(request);
```

SDK for JavaScript

The following SDK for JavaScript code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
const REGION = 'ap-southeast-2'

const s3ControlClient = new S3ControlClient({
  region: REGION
})

export const run = async () => {
  try {
    const data = await s3ControlClient.send(
      new SubmitMultiRegionAccessPointRoutesCommand({
        AccountId: '111122223333',
        Mrap: 'arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap',
        RouteUpdates: [
          {
            Region: 'eu-west-1',
            TrafficDialPercentage: 100,
          },
          {
            Region: 'ca-central-1',
            Bucket: 'amzn-s3-demo-bucket1',
            TrafficDialPercentage: 0,
          },
        ],
      })
    console.log(data)
  } catch (err) {
    console.error(err)
  }
}
```

```
        })
    )
    console.log('Success', data)
    return data
} catch (err) {
    console.log('Error', err)
}
}

run()
```

SDK for Python

The following SDK for Python code updates your Multi-Region Access Point route configuration. To use this example syntax, replace the *user input placeholders* with your own information.

```
s3.submit_multi_region_access_point_routes(
    AccountId=111122223333,
    Mrap=arn:aws:s3:::111122223333:accesspoint/abcdef0123456.mrap,
    RouteUpdates= [
        {
            'Bucket': amzn-s3-demo-bucket,
            'Region': ap-southeast-2,
            'TrafficDialPercentage': 10
    }])
])
```

Add an object to a bucket in your Multi-Region Access Point

To add an object to the bucket that's associated with the Multi-Region Access Point, you can use the [PutObject](#) operation. To keep all buckets in the Multi-Region Access Point in sync, enable [Cross-Region Replication](#).

Note

To use this operation, you must have the s3:PutObject permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permission requirements, see [Permissions](#).

AWS CLI

The following example data plane request uploads *example.txt* to the specified Multi-Region Access Point. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api put-object --bucket  
arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap --key example.txt --  
body example.txt
```

SDK for Java

```
S3Client s3Client = S3Client.builder()  
    .build();  
  
PutObjectRequest objectRequest = PutObjectRequest.builder()  
    .bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")  
    .key("example.txt")  
    .build();  
  
s3Client.putObject(objectRequest, RequestBody.fromString("Hello S3!));
```

SDK for JavaScript

```
const client = new S3Client({});  
  
async function putObjectExample() {  
    const command = new PutObjectCommand({  
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",  
        Key: "example.txt",  
        Body: "Hello S3!",  
    });  
  
    try {  
        const response = await client.send(command);  
        console.log(response);  
    } catch (err) {  
        console.error(err);  
    }  
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.put_object(
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap',
    Key='example.txt',
    Body='Hello S3!'
)
```

Retrieve objects from your Multi-Region Access Point

To retrieve objects from the Multi-Region Access Point, you can use the [GetObject](#) operation.

Note

To use this API operation, you must have the `s3:GetObject` permission for the Multi-Region Access Point. For more information about Multi-Region Access Point permissions requirements, see [Permissions](#).

AWS CLI

The following example data plane request retrieves `example.txt` from the specified Multi-Region Access Point and downloads it as `downloaded_example.txt`. To use this example, replace the `user input placeholders` with your own information.

```
aws s3api get-object --bucket
    arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap --
    key example.txt downloaded_example.txt
```

SDK for Java

```
S3Client s3 = S3Client
    .builder()
    .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")
```

```
.key("example.txt")
.build();

s3Client.getObject(getObjectRequest);
```

SDK for JavaScript

```
const client = new S3Client({})

async function getObjectExample() {
    const command = new GetObjectCommand({
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",
        Key: "example.txt"
    });

    try {
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.get_object(
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456',
    Key='example.txt'
)
```

List objects that are stored in a bucket underlying your Multi-Region Access Point

To return a list of objects that are stored in a bucket underlying your Multi-Region Access Point, use the [ListObjectsV2](#) operation. In the following example command, all objects for the specified Multi-Region Access Point are listed by using the ARN for the Multi-Region Access Point. In this case, the Multi-Region Access Point ARN is:

`arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap`

Note

To use this API operation, you must have the `s3>ListBucket` permission for the Multi-Region Access Point and the underlying bucket. For more information about Multi-Region Access Point permissions requirements, see [Permissions](#).

AWS CLI

The following example data plane request lists the objects in the bucket that underlies the Multi-Region Access Point that's specified by the ARN. To use this example, replace the *user input placeholders* with your own information.

```
aws s3api list-objects-v2 --bucket  
arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap
```

SDK for Java

```
S3Client s3Client = S3Client.builder()  
    .build();  
  
String bucketName = "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap";  
  
ListObjectsV2Request listObjectsRequest = ListObjectsV2Request  
    .builder()  
    .bucket(bucketName)  
    .build();  
  
s3Client.listObjectsV2(listObjectsRequest);
```

SDK for JavaScript

```
const client = new S3Client({});  
  
async function listObjectsExample() {  
    const command = new ListObjectsV2Command({  
        Bucket: "arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap",  
    });  
  
    try {
```

```
        const response = await client.send(command);
        console.log(response);
    } catch (err) {
        console.error(err);
    }
}
```

SDK for Python

```
import boto3

client = boto3.client('s3')
client.list_objects_v2(
    Bucket='arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap'
)
```

Use a presigned URL with Multi-Region Access Points

You can use a presigned URL to generate a URL that allows others to access your Amazon S3 buckets through an Amazon S3 Multi-Region Access Point. When you create a presigned URL, you associate it with a specific object action, such as an S3 upload (`PutObject`) or an S3 download (`GetObject`). You can share the presigned URL, and anyone with access to it can perform the action embedded in the URL as if they were the original signing user.

Presigned URLs have an expiration date. When the expiration time is reached, the URL will no longer work.

Before you use S3 Multi-Region Access Points with presigned URLs, check the [AWS SDK compatibility](#) with the SigV4A algorithm. Verify that your SDK version supports SigV4A as the signing implementation that is used to sign the global AWS Region requests. For more information about using presigned URLs with Amazon S3, see [Sharing objects by using presigned URLs](#).

The following examples show how you can use Multi-Region Access Points with presigned URLs. To use these examples, replace the *user input placeholders* with your own information.

AWS CLI

```
aws s3 presign
arn:aws:s3:::123456789012:accesspoint/MultiRegionAccessPoint_alias/example-file.txt
```

SDK for Python

```
import logging
import boto3
from botocore.exceptions import ClientError

s3_client = boto3.client('s3', aws_access_key_id='xxx', aws_secret_access_key='xxx')
s3_client.generate_presigned_url(HttpMethod='PUT', ClientMethod="put_object",
    Params={'Bucket': 'arn:aws:s3:::123456789012:accesspoint/' +
    'abcdef0123456.mrap', 'Key': 'example-file'})
```

SDK for Java

```
S3Presigner s3Presigner = S3Presigner.builder()
    .credentialsProvider(StsAssumeRoleCredentialsProvider.builder()
        .refreshRequest(assumeRole)
        .stsClient(stsClient)
        .build())
    .build();

GetObjectRequest getObjectRequest = GetObjectRequest.builder()
    .bucket("arn:aws:s3:::123456789012:accesspoint/abcdef0123456.mrap")
    .key("example-file")
    .build();

GetObjectPresignRequest preSignedReq = GetObjectPresignRequest.builder()
    .getObjectRequest(getObjectRequest)
    .signatureDuration(Duration.ofMinutes(10))
    .build();

PresignedGetObjectRequest presignedGetObjectRequest =
    s3Presigner.presignGetObject(preSignedReq);
```

Note

To use SigV4A with temporary security credentials—for example, when using IAM roles—make sure that you request the temporary credentials from a Regional endpoint in AWS Security Token Service (AWS STS), instead of a global endpoint. If you use the global endpoint for AWS STS (`sts.amazonaws.com`), AWS STS will generate temporary

credentials from a global endpoint, which isn't supported by Sig4A. As a result, you'll get an error. To resolve this issue, use any of the listed [Regional endpoints for AWS STS](#).

Use a bucket that's configured with Requester Pays with Multi-Region Access Points

If an S3 bucket that is associated with your Multi-Region Access Points is [configured to use Requester Pays](#), the requester will pay for the bucket request, the download, and any Multi-Region Access Points related costs. For more information, see [Amazon S3 pricing](#).

Here's an example of a data plane request to a Multi-Region Access Point that is connected to a Requester Pays bucket.

AWS CLI

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify `--request-payer requester` as part of your [get-object](#) request. You must also specify the name of the file in the bucket and the location where the downloaded file should be stored.

```
aws s3api get-object --bucket MultiRegionAccessPoint_ARN --request-payer requester  
--key example-file-in-bucket.txt example-location-of-downloaded-file.txt
```

SDK for Java

To download objects from a Multi-Region Access Point that is connected to a Requester Pays bucket, you must specify the `RequestPayer.REQUESTER` as part of your `GetObject` request. You must also specify the name of the file in the bucket, as well as the location where it should be stored.

```
GetObjectResponse getObjectResponse = s3Client.getObject(GetObjectRequest.builder()  
    .key("example-file.txt")  
    .bucket("arn:aws:s3:::  
123456789012:accesspoint/abcdef0123456.mrap")  
    .requestPayer(RequestPayer.REQUESTER)  
    .build()  
).response();
```

Monitoring and logging requests made through a Multi-Region Access Point to underlying resources

Amazon S3 logs requests made through Multi-Region Access Points and requests made to the API operations that manage them, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. Requests made to Amazon S3 through a Multi-Region Access Point appear in your Amazon S3 server access logs and AWS CloudTrail logs with the Multi-Region Access Point hostname. An access point's hostname takes the form `MRAP_alias.accesspoint.s3-global.amazonaws.com`. For example, suppose that you have the following bucket and Multi-Region Access Point configuration:

- A bucket named `my-bucket-usw2` in the Region `us-west-2` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-aps1` in the Region `ap-south-1` that contains the object `my-image.jpg`.
- A bucket named `my-bucket-euc1` in the Region `eu-central-1` that doesn't contain an object named `my-image.jpg`.
- A Multi-Region Access Point named `my-mrap` with the alias `mfzwi23gnjvgw.mrap` that is configured to fulfill requests from all three buckets.
- Your AWS account ID is `123456789012`.

A request made to retrieve `my-image.jpg` directly through any of the buckets appears in your logs with a hostname of `bucket_name.s3.Region.amazonaws.com`.

If you make the request through the Multi-Region Access Point instead, Amazon S3 first determines which of the buckets in the different Regions is closest. After Amazon S3 determines which bucket to use to fulfill the request, it sends the request to that bucket and logs the operation by using the Multi-Region Access Point hostname. In this example, if Amazon S3 relays the request to `my-bucket-aps1`, your logs will reflect a successful GET request for `my-image.jpg` from `my-bucket-aps1`, using a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Important

Multi-Region Access Points aren't aware of the data contents of the underlying buckets. Therefore, the bucket that gets the request might not contain the requested data. For

example, if Amazon S3 determines that the my-bucket-euc1 bucket is the closest, your logs will reflect a failed GET request for my-image.jpg from my-bucket-euc1, using a hostname of mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com. If the request was routed to my-bucket-usw2 instead, your logs would indicate a successful GET request.

For more information about Amazon S3 server access logs, see [Logging requests with server access logging](#). For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the [AWS CloudTrail User Guide](#).

Monitoring and logging requests made to Multi-Region Access Point management API operations

Amazon S3 provides several API operations to manage Multi-Region Access Points, such as CreateMultiRegionAccessPoint and GetMultiRegionAccessPointPolicy. When you make requests to these API operations by using the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, Amazon S3 processes these requests asynchronously. Provided that you have the appropriate permissions for the request, Amazon S3 returns a token for these requests. You can use this token with DescribeAsyncOperation to help you to view the status of ongoing asynchronous operations. Amazon S3 processes DescribeAsyncOperation requests synchronously. To view the status of asynchronous requests, you can use the Amazon S3 console, AWS CLI, SDKs, or REST API.

Note

The console displays only the status of asynchronous requests that were made within the previous 14 days. To view the status of older requests, use the AWS CLI, SDKs, or REST API.

Asynchronous management operations can be in one of several states:

NEW

Amazon S3 has received the request and is preparing to perform the operation.

IN_PROGRESS

Amazon S3 is currently performing the operation.

SUCCESS

The operation succeeded. The response includes relevant information, such as the Multi-Region Access Point alias for a `CreateMultiRegionAccessPoint` request.

FAILED

The operation failed. The response includes an error message that indicates the reason for the request failure.

Using AWS CloudTrail with Multi-Region Access Points

You can use AWS CloudTrail to view, search, download, archive, analyze, and respond to account activity across your AWS infrastructure. With Multi-Region Access Points and CloudTrail logging, you can identify the following:

- Who or what took which action
- Which resources were acted upon
- When the event occurred
- Other details regarding the event

You can use this logging information to help you analyze and respond to activity that occurred through your Multi-Region Access Points.

How to set up AWS CloudTrail for Multi-Region Access Points

To enable CloudTrail logging for any operations related to creating or maintaining Multi-Region Access Points, you must configure CloudTrail logging to record the events in the US West (Oregon) Region. You must set up your logging configuration this way regardless of which Region you are in when making the request, or which Regions the Multi-Region Access Point supports. All requests to create or maintain a Multi-Region Access Point are routed through the US West (Oregon) Region. We recommend that you either add this Region to an existing trail or create a new trail that contains this Region and all the Regions associated with the Multi-Region Access Point.

Amazon S3 logs all requests made through a Multi-Region Access Point and requests made to the API operations that manage access points, such as `CreateMultiRegionAccessPoint` and `GetMultiRegionAccessPointPolicy`. When you log these requests through a Multi-Region Access Point, they appear in your AWS CloudTrail logs with the hostname of the Multi-Region Access Point. For example, if you make requests to a bucket through a Multi-Region Access Point

with the alias `mfzwi23gnjvgw.mrap`, the entries in the CloudTrail log will have a hostname of `mfzwi23gnjvgw.mrap.accesspoint.s3-global.amazonaws.com`.

Multi-Region Access Points route requests to the closest bucket. Because of this behavior, when you are looking at the CloudTrail logs for a Multi-Region Access Point, you will see requests being made to the underlying buckets. Some of those requests might be direct requests to the bucket that are not routed through the Multi-Region Access Point. Keep this fact in mind when reviewing traffic. When a bucket is in a Multi-Region Access Point, requests can still be made to that bucket directly without going through the Multi-Region Access Point.

There are asynchronous events involved with creating and managing Multi-Region Access Points. Asynchronous requests don't have completion events in the CloudTrail log. For more information about asynchronous requests, see [Monitoring and logging requests made to Multi-Region Access Point management API operations](#).

For more information about AWS CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

Retaining multiple versions of objects with S3 Versioning

Versioning in Amazon S3 is a means of keeping multiple variants of an object in the same bucket. You can use the S3 Versioning feature to preserve, retrieve, and restore every version of every object stored in your buckets. With versioning you can recover more easily from both unintended user actions and application failures. After versioning is enabled for a bucket, if Amazon S3 receives multiple write requests for the same object simultaneously, it stores all of those objects.

Versioning-enabled buckets can help you recover objects from accidental deletion or overwrite. For example, if you delete an object, Amazon S3 inserts a delete marker instead of removing the object permanently. The delete marker becomes the current object version. If you overwrite an object, it results in a new object version in the bucket. You can always restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).

By default, S3 Versioning is disabled on buckets, and you must explicitly enable it. For more information, see [Enabling versioning on buckets](#).

Note

- The SOAP API does not support S3 Versioning. SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features are not supported for SOAP.

- Normal Amazon S3 rates apply for every version of an object stored and transferred. Each version of an object is the entire object; it is not just a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Unversioned, versioning-enabled, and versioning-suspended buckets

Buckets can be in one of three states:

- Unversioned (the default)
- Versioning-enabled
- Versioning-suspended

You enable and suspend versioning at the bucket level. After you version-enable a bucket, it can never return to an unversioned state. But you can *suspend* versioning on that bucket.

The versioning state applies to all (never some) of the objects in that bucket. When you enable versioning in a bucket, all new objects are versioned and given a unique version ID. Objects that already existed in the bucket at the time versioning was enabled will thereafter *always* be versioned and given a unique version ID when they are modified by future requests. Note the following:

- Objects that are stored in your bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests. For more information, see [Working with objects in a versioning-enabled bucket](#).
- The bucket owner (or any user with appropriate permissions) can suspend versioning to stop accruing object versions. When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. For more information, see [Working with objects in a versioning-suspended bucket](#).

Using S3 Versioning with S3 Lifecycle

To customize your data retention approach and control storage costs, use object versioning with S3 Lifecycle. For more information, see [Managing the lifecycle of objects](#). For information about

creating S3 Lifecycle configurations using the AWS Management Console, AWS CLI, AWS SDKs, or the REST API, see [Setting an S3 Lifecycle configuration on a bucket](#).

Important

If you have an object expiration lifecycle configuration in your unversioned bucket and you want to maintain the same permanent delete behavior when you enable versioning, you must add a noncurrent expiration configuration. The noncurrent expiration lifecycle configuration manages the deletes of the noncurrent object versions in the versioning-enabled bucket. (A versioning-enabled bucket maintains one current, and zero or more noncurrent, object versions.) For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

For information about working with S3 Versioning, see the following topics.

Topics

- [How S3 Versioning works](#)
- [Enabling versioning on buckets](#)
- [Configuring MFA delete](#)
- [Working with objects in a versioning-enabled bucket](#)
- [Working with objects in a versioning-suspended bucket](#)
- [Troubleshooting versioning](#)

How S3 Versioning works

You can use S3 Versioning to keep multiple versions of an object in one bucket so that you can restore objects that are accidentally deleted or overwritten. For example, if you apply S3 Versioning to a bucket, the following changes occur:

- If you delete an object, instead of removing the object permanently, Amazon S3 inserts a delete marker, which becomes the current object version. You can then restore the previous version. For more information, see [Deleting object versions from a versioning-enabled bucket](#).
- If you overwrite an object, Amazon S3 adds a new object version in the bucket. The previous version remains in the bucket and becomes a noncurrent version. You can restore the previous version.

Note

Normal Amazon S3 rates apply for every version of an object that is stored and transferred. Each version of an object is the entire object; it is not a diff from the previous version. Thus, if you have three versions of an object stored, you are charged for three objects.

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [Bucket configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes an Enabled status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

Note

When you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. While this change is propagating, you may encounter intermittent HTTP 404 NoSuchKey errors for requests to objects created or updated after enabling versioning. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE) on objects in the bucket.

The bucket owner and all authorized AWS Identity and Access Management (IAM) users can enable versioning. The bucket owner is the AWS account that created the bucket. For more information about permissions, see [Identity and Access Management for Amazon S3](#).

For more information about enabling and disabling S3 Versioning by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or REST API, see [the section called "Enabling versioning on buckets"](#).

Topics

- [Version IDs](#)
- [Versioning workflows](#)

Version IDs

If you enable versioning for a bucket, Amazon S3 automatically generates a unique version ID for the object that is being stored. For example, in one bucket you can have two objects with the same key (object name) but different version IDs, such as photo.gif (version 111111) and photo.gif (version 121212).

Diagram depicting a versioning-enabled bucket that has two objects with the same key but different version IDs.

Each object has a version ID, whether or not S3 Versioning is enabled. If S3 Versioning is not enabled, Amazon S3 sets the value of the version ID to null. If you enable S3 Versioning, Amazon S3 assigns a version ID value for the object. This value distinguishes that object from other versions of the same key.

When you enable S3 Versioning on an existing bucket, objects that are already stored in the bucket are unchanged. Their version IDs (null), contents, and permissions remain the same. After you enable S3 Versioning, each object that is added to the bucket gets a version ID, which distinguishes it from other versions of the same key.

Only Amazon S3 generates version IDs, and they cannot be edited. Version IDs are Unicode, UTF-8 encoded, URL-ready, opaque strings that are no more than 1,024 bytes long. The following is an example:

3sL4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY+MTRCx3vjVBH40Nr8X8gdRQBpUMLUo

 **Note**

For simplicity, the other examples in this topic use much shorter IDs.

Versioning workflows

When you PUT an object in a versioning-enabled bucket, the noncurrent version is not overwritten. As shown in the following figure, when a new version of photo.gif is PUT into a bucket that already contains an object with the same name, the following behavior occurs:

- The original object (ID = 111111) remains in the bucket.
- Amazon S3 generates a new version ID (121212), and adds this newer version of the object to the bucket.

With this functionality, you can retrieve a previous version of an object if an object has been accidentally overwritten or deleted.

When you DELETE an object, all versions remain in the bucket, and Amazon S3 inserts a delete marker, as shown in the following figure.

The delete marker becomes the current version of the object. By default, GET requests retrieve the most recently stored version. Performing a GET Object request when the current version is a delete marker returns a 404 Not Found error, as shown in the following figure.

However, you can GET a noncurrent version of an object by specifying its version ID. In the following figure, you GET a specific object version, 111111. Amazon S3 returns that object version even though it's not the current version.

For more information, see [Retrieving object versions from a versioning-enabled bucket](#).

You can permanently delete an object by specifying the version that you want to delete. Only the owner of an Amazon S3 bucket or an authorized IAM user can permanently delete a version. If your DELETE operation specifies the `versionId`, that object version is permanently deleted, and Amazon S3 doesn't insert a delete marker.

You can add more security by configuring a bucket to enable multi-factor authentication (MFA) delete. When you enable MFA delete for a bucket, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket. For more information, see [Configuring MFA delete](#).

When are new versions created for an object?

New versions of objects are created only when you PUT a new object. Be aware that certain actions, such as `CopyObject`, work by implementing a PUT operation.

Some actions that modify the current object don't create a new version because they don't PUT a new object. This includes actions such as changing the tags on an object.

Important

If you notice a significant increase in the number of HTTP 503 (Service Unavailable) responses received for Amazon S3 PUT or DELETE object requests to a bucket that has S3 Versioning enabled, you might have one or more objects in the bucket for which there are millions of versions. For more information, see the S3 Versioning section of [Troubleshooting versioning](#).

Enabling versioning on buckets

You can use S3 Versioning to keep multiple versions of an object in one bucket. This section provides examples of how to enable versioning on a bucket using the console, REST API, AWS SDKs, and AWS Command Line Interface (AWS CLI).

Note

When you enable versioning on a bucket for the first time, it might take a short amount of time for the change to be fully propagated. While this change is propagating, you may encounter intermittent HTTP 404 `NoSuchKey` errors for requests to objects created or

updated after enabling versioning. We recommend that you wait for 15 minutes after enabling versioning before issuing write operations (PUT or DELETE) on objects in the bucket.

For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#). For information about working with objects that are in versioning-enabled buckets, see [Working with objects in a versioning-enabled bucket](#).

To learn more about how to use S3 Versioning to protect data, see [Tutorial: Protecting data on Amazon S3 against accidental deletion or application bugs using S3 Versioning, S3 Object Lock, and S3 Replication](#).

Each S3 bucket that you create has a *versioning* subresource associated with it. (For more information, see [Bucket configuration options](#).) By default, your bucket is *unversioned*, and the versioning subresource stores the empty versioning configuration, as follows.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</VersioningConfiguration>
```

To enable versioning, you can send a request to Amazon S3 with a versioning configuration that includes a status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>Enabled</Status>
</VersioningConfiguration>
```

To suspend versioning, you set the status value to Suspended.

The bucket owner and all authorized users can enable versioning. The bucket owner is the AWS account that created the bucket (the root account). For more information about permissions, see [Identity and Access Management for Amazon S3](#).

The following sections provide more detail about enabling S3 Versioning using the console, AWS CLI, and the AWS SDKs.

Using the S3 console

Follow these steps to use the AWS Management Console to enable versioning on an S3 bucket.

To enable or disable versioning on an S3 general purpose bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable versioning for.
4. Choose **Properties**.
5. Under **Bucket Versioning**, choose **Edit**.
6. Choose **Suspend** or **Enable**, and then choose **Save changes**.

Note

You can use AWS multi-factor authentication (MFA) with versioning. When you use MFA with versioning, you must provide your AWS account's access keys and a valid code from the account's MFA device to permanently delete an object version or suspend or reactivate versioning.

To use MFA with versioning, you enable MFA Delete. However, you can't enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API. For more information, see [Configuring MFA delete](#).

Using the AWS CLI

The following example enables versioning on an S3 general purpose bucket.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled
```

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "SERIAL 123456"
```

Note

Using MFA delete requires an approved physical or virtual authentication device. For more information about using MFA delete in Amazon S3, see [Configuring MFA delete](#).

For more information about enabling versioning using the AWS CLI, see [put-bucket-versioning](#) in the *AWS CLI Command Reference*.

Using the AWS SDKs

The following examples enable versioning on a bucket and then retrieve versioning status using the AWS SDK for Java and the AWS SDK for .NET. For information about using other AWS SDKs, see the [AWS Developer Center](#).

.NET

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using System;
using Amazon.S3;
using Amazon.S3.Model;

namespace s3.amazonaws.com.docsamples
{
    class BucketVersioningConfiguration
    {
        static string bucketName = "*** bucket name ***";

        public static void Main(string[] args)
        {
            using (var client = new AmazonS3Client(Amazon.RegionEndpoint.USEast1))
            {
                try
                {
                    EnableVersioningOnBucket(client);

    {
        BucketName = bucketName
}
```

```
    };

        GetBucketVersioningResponse response =
client.GetBucketVersioning(request);
        return response.VersioningConfig.Status;
    }
}

}
```

Java

For instructions on how to create and test a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```
import java.io.IOException;

import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Region;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3Client;
import com.amazonaws.services.s3.model.AmazonS3Exception;
import com.amazonaws.services.s3.model.BucketVersioningConfiguration;
import com.amazonaws.services.s3.model.SetBucketVersioningConfigurationRequest;

public class BucketVersioningConfigurationExample {
    public static String bucketName = "*** bucket name ***";
    public static AmazonS3Client s3Client;

    public static void main(String[] args) throws IOException {
        s3Client = new AmazonS3Client(new ProfileCredentialsProvider());
        s3Client.setRegion(Region.getRegion(Regions.US_EAST_1));
        try {

            // 1. Enable versioning on the bucket.
            BucketVersioningConfiguration configuration =
                new BucketVersioningConfiguration().withStatus("Enabled");

            SetBucketVersioningConfigurationRequest setBucketVersioningConfigurationRequest =
                new SetBucketVersioningConfigurationRequest(bucketName, configuration);

            s3Client.setBucketVersioningConfiguration(setBucketVersioningConfigurationRequest);
```

```
// 2. Get bucket versioning configuration information.  
BucketVersioningConfiguration conf =  
s3Client.getBucketVersioningConfiguration(bucketName);  
System.out.println("bucket versioning configuration status: " +  
conf.getStatus());  
  
} catch (AmazonS3Exception amazonS3Exception) {  
    System.out.format("An Amazon S3 error occurred. Exception: %s",  
amazonS3Exception.toString());  
} catch (Exception ex) {  
    System.out.format("Exception: %s", ex.toString());  
}  
}  
}  
}
```

Python

The following Python code example creates an Amazon S3 bucket, enables it for versioning, and configures a lifecycle that expires noncurrent object versions after 7 days.

```
def create_versioned_bucket(bucket_name, prefix):  
    """  
    Creates an Amazon S3 bucket, enables it for versioning, and configures a  
    lifecycle  
    that expires noncurrent object versions after 7 days.  
  
    Adding a lifecycle configuration to a versioned bucket is a best practice.  
    It helps prevent objects in the bucket from accumulating a large number of  
    noncurrent versions, which can slow down request performance.  
  
    Usage is shown in the usage_demo_single_object function at the end of this  
    module.  
  
    :param bucket_name: The name of the bucket to create.  
    :param prefix: Identifies which objects are automatically expired under the  
        configured lifecycle rules.  
    :return: The newly created bucket.  
    """  
    try:  
        bucket = s3.create_bucket(  
            Bucket=bucket_name,  
            CreateBucketConfiguration={
```

```
        "LocationConstraint": s3.meta.client.meta.region_name
    },
)
logger.info("Created bucket %s.", bucket.name)
except ClientError as error:
    if error.response["Error"]["Code"] == "BucketAlreadyOwnedByYou":
        logger.warning("Bucket %s already exists! Using it.", bucket_name)
        bucket = s3.Bucket(bucket_name)
    else:
        logger.exception("Couldn't create bucket %s.", bucket_name)
        raise

try:
    bucket.Versioning().enable()
    logger.info("Enabled versioning on bucket %s.", bucket.name)
except ClientError:
    logger.exception("Couldn't enable versioning on bucket %s.", bucket.name)
    raise

try:
    expiration = 7
    bucket.LifecycleConfiguration().put(
        LifecycleConfiguration={
            "Rules": [
                {
                    "Status": "Enabled",
                    "Prefix": prefix,
                    "NoncurrentVersionExpiration": {"NoncurrentDays": expiration},
                }
            ]
        }
    )
    logger.info(
        "Configured lifecycle to expire noncurrent versions after %s days "
        "on bucket %s.",
        expiration,
        bucket.name,
    )
except ClientError as error:
    logger.warning(
        "Couldn't configure lifecycle on bucket %s because %s. "
        "Continuing anyway.",
        bucket.name,
```

```
        error,  
    )  
  
    return bucket
```

Configuring MFA delete

When working with S3 Versioning in Amazon S3 buckets, you can optionally add another layer of security by configuring a bucket to enable *MFA (multi-factor authentication) delete*. When you do this, the bucket owner must include two forms of authentication in any request to delete a version or change the versioning state of the bucket.

MFA delete requires additional authentication for either of the following operations:

- Changing the versioning state of your bucket
- Permanently deleting an object version

MFA delete requires two forms of authentication together:

- Your security credentials
- The concatenation of a valid serial number, a space, and the six-digit code displayed on an approved authentication device

MFA delete thus provides added security if, for example, your security credentials are compromised. MFA delete can help prevent accidental bucket deletions by requiring the user who initiates the delete action to prove physical possession of an MFA device with an MFA code and adding an extra layer of friction and security to the delete action.

To identify buckets that have MFA delete enabled, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Assessing your storage activity and usage with S3 Storage Lens](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

The bucket owner, the AWS account that created the bucket (root account), and all authorized users can enable versioning. However, only the bucket owner (root account) can enable MFA delete. For more information, see [Securing Access to AWS Using MFA](#) on the AWS Security Blog.

Note

To use MFA delete with versioning, you enable MFA Delete. However, you cannot enable MFA Delete using the AWS Management Console. You must use the AWS Command Line Interface (AWS CLI) or the API.

For examples of using MFA delete with versioning, see the examples section in the topic [Enabling versioning on buckets](#).

You cannot use MFA delete with lifecycle configurations. For more information about lifecycle configurations and how they interact with other configurations, see [How S3 Lifecycle interacts with other bucket configurations](#).

To enable or disable MFA delete, you use the same API that you use to configure versioning on a bucket. Amazon S3 stores the MFA delete configuration in the same *versioning* subresource that stores the bucket's versioning status.

```
<VersioningConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Status>VersioningState</Status>
  <MfaDelete>MfaDeleteState</MfaDelete>
</VersioningConfiguration>
```

To use MFA delete, you can use either a hardware or virtual MFA device to generate an authentication code. The following example shows a generated authentication code displayed on a hardware device.

MFA delete and MFA-protected API access are features intended to provide protection for different scenarios. You configure MFA delete on a bucket to help ensure that the data in your bucket cannot be accidentally deleted. MFA-protected API access is used to enforce another authentication factor (MFA code) when accessing sensitive Amazon S3 resources. You can require any operations against these Amazon S3 resources to be done with temporary credentials created using MFA. For an example, see [Requiring MFA](#).

For more information about how to purchase and activate an authentication device, see [Multi-factor authentication](#).

To enable S3 Versioning and configure MFA delete

Using the AWS CLI

The serial number is the number that uniquely identifies the MFA device. For physical MFA devices, this is the unique serial number that's provided with the device. For virtual MFA devices, the serial number is the device ARN.

The following example enables S3 Versioning and multi-factor authentication (MFA) delete on a bucket.

```
aws s3api put-bucket-versioning --bucket amzn-s3-demo-bucket1 --versioning-configuration Status=Enabled,MFADelete=Enabled --mfa "SERIAL 123456"
```

Using the REST API

For more information about specifying MFA delete using the Amazon S3 REST API, see [PutBucketVersioning](#) *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-enabled bucket

Objects that are stored in an Amazon S3 bucket before you set the versioning state have a version ID of null. When you enable versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles the objects in future requests.

Transitioning object versions

You can define lifecycle configuration rules for objects that have a well-defined lifecycle to transition object versions to the S3 Glacier Flexible Retrieval storage class at a specific time in the object's lifetime. For more information, see [Managing the lifecycle of objects](#).

The topics in this section explain various object operations in a versioning-enabled bucket. For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

Topics

- [Adding objects to versioning-enabled buckets](#)
- [Listing objects in a versioning-enabled bucket](#)
- [Retrieving object versions from a versioning-enabled bucket](#)
- [Deleting object versions from a versioning-enabled bucket](#)
- [Configuring versioned object permissions](#)

Adding objects to versioning-enabled buckets

After you enable versioning on a bucket, Amazon S3 automatically adds a unique version ID to every object stored (using PUT, POST, or CopyObject) in the bucket.

The following figure shows that Amazon S3 adds a unique version ID to an object when it is added to a versioning-enabled bucket.

i Note

The version ID values that Amazon S3 assigns are URL safe (can be included as part of a URI).

For more information about versioning, see [Retaining multiple versions of objects with S3 Versioning](#). You can add object versions to a versioning-enabled bucket using the console, AWS SDKs, and REST API.

Using the console

For instructions, see [Uploading objects](#).

Using the AWS SDKs

For examples of uploading objects using the AWS SDKs for Java, .NET, and PHP, see [Uploading objects](#). The examples for uploading objects in nonversioned and versioning-enabled buckets are the same, although in the case of versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Using the REST API

To add objects to versioning-enabled buckets

1. Enable versioning on a bucket using a PutBucketVersioning request.

For more information, see [PutBucketVersioning](#) in the *Amazon Simple Storage Service API Reference*.

2. Send a PUT, POST, or CopyObject request to store an object in the bucket.

When you add an object to a versioning-enabled bucket, Amazon S3 returns the version ID of the object in the `x-amz-version-id` response header, as shown in the following example.

```
x-amz-version-id: 3/L4kqtJlcpXroDTDmJ+rmSpXd3dIbrHY
```

Listing objects in a versioning-enabled bucket

This section provides examples of listing object versions from a versioning-enabled bucket. Amazon S3 stores object version information in the `versions` subresource that is associated with the bucket. For more information, see [Bucket configuration options](#). In order to list the objects in a versioning-enabled bucket, you need the `ListBucketVersions` permission.

Using the S3 console

Follow these steps to use the Amazon S3 console to see the different versions of an object.

To see multiple versions of an object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. To see a list of the versions of the objects in the bucket, choose the **Show versions** switch.

For each object version, the console shows a unique version ID, the date and time the object version was created, and other properties. (Objects stored in your bucket before you set the versioning state have a version ID of **null**.)

To list the objects without the versions, choose the **List versions** switch.

You also can view, download, and delete object versions in the object overview pane on the console. For more information, see [Viewing object properties in the Amazon S3 console](#).

 **Note**

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

 **Important**

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

The examples in this section show how to retrieve an object listing from a versioning-enabled bucket. Each request returns up to 1,000 versions, unless you specify a lower number. If the bucket contains more versions than this limit, you send a series of requests to retrieve the list of all versions. This process of returning results in "pages" is called *pagination*.

To show how pagination works, the examples limit each response to two object versions. After retrieving the first page of results, each example checks to determine whether the version list was truncated. If it was, the example continues retrieving pages until all versions have been retrieved.

Note

The following examples also work with a bucket that isn't versioning-enabled, or for objects that don't have individual versions. In those cases, Amazon S3 returns the object listing with a version ID of null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Java

For instructions on creating and testing a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;

        }

        static async Task GetObjectListWithAllVersionsAsync()
        {
            try
            {
                ListVersionsRequest request = new ListVersionsRequest()
                {
                    BucketName = bucketName,
                    // You can optionally specify key name prefix in the request
                    // if you want list of object versions of a specific object.

                    // For this example we limit response to return list of 2
                    versions.
                    MaxKeys = 2
                };
                do
                {
                    ListVersionsResponse response = await
s3Client.ListVersionsAsync(request);
                    // Process response.
                    foreach (S3ObjectVersion entry in response.Versions)
                    {
                        Console.WriteLine("key = {0} size = {1}",
                            entry.Key, entry.Size);
                    }
                }
            }
        }
    }
}
```

```
// If response is truncated, set the marker to get the next
// set of keys.
if (response.IsTruncated)
{
    request.KeyMarker = response.NextKeyMarker;
    request.VersionIdMarker = response.NextVersionIdMarker;
}
else
{
    request = null;
}
} while (request != null);
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}
}
}
```

Using the REST API

Example — Listing all object versions in a bucket

To list all the versions of all the objects in a bucket, you use the `versions` subresource in a GET Bucket request. Amazon S3 can retrieve a maximum of 1,000 objects, and each object version counts fully as an object. Therefore, if a bucket contains two keys (for example, `photo.gif` and `picture.jpg`), and the first key has 990 versions and the second key has 400 versions, a single request would retrieve all 990 versions of `photo.gif` and only the most recent 10 versions of `picture.jpg`.

Amazon S3 returns object versions in the order in which they were stored, with the most recently stored returned first.

In a GET Bucket request, include the `versions` subresource.

```
GET /?versions HTTP/1.1
Host: bucketName.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 +0000
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Example — Retrieving all versions of a key

To retrieve a subset of object versions, you use the request parameters for GET Bucket. For more information, see [GET Bucket](#).

1. Set the `prefix` parameter to the key of the object that you want to retrieve.
2. Send a GET Bucket request using the `versions` subresource and `prefix`.

```
GET /?versions&prefix=objectName HTTP/1.1
```

Example — Retrieving objects using a prefix

The following example retrieves objects whose key is or begins with `myObject`.

```
GET /?versions&prefix=myObject HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can use the other request parameters to retrieve a subset of all versions of the object. For more information, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

Example — Retrieving a listing of additional objects if the response is truncated

If the number of objects that could be returned in a GET request exceeds the value of `max-keys`, the response contains `<isTruncated>true</isTruncated>`, and includes the first key (in `NextKeyMarker`) and the first version ID (in `NextVersionIdMarker`) that satisfy the request, but were not returned. You use those returned values as the starting position in a subsequent request to retrieve the additional objects that satisfy the GET request.

Use the following process to retrieve additional objects that satisfy the original GET Bucket `versions` request from a bucket. For more information about `key-marker`, `version-id-`

marker, NextKeyMarker, and NextVersionIdMarker, see [GET Bucket](#) in the *Amazon Simple Storage Service API Reference*.

The following are additional responses that satisfy the original GET request:

- Set the value of key-marker to the key returned in NextKeyMarker in the previous response.
- Set the value of version-id-marker to the version ID returned in NextVersionIdMarker in the previous response.
- Send a GET Bucket versions request using key-marker and version-id-marker.

Example — Retrieving objects starting with a specified key and version ID

```
GET /?versions&key-marker=myObject&version-id-marker=298459348571 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

Using the AWS CLI

The following command returns metadata about all versions of the objects in a bucket.

```
aws s3api list-object-versions --bucket amzn-s3-demo-bucket1
```

For more information about `list-object-versions` see [list-object-versions](#) in the *AWS CLI Command Reference*.

Retrieving object versions from a versioning-enabled bucket

Versioning in Amazon S3 is a way of keeping multiple variants of an object in the same bucket. A simple GET request retrieves the current version of an object. The following figure shows how GET returns the current version of the object, `photo.gif`.

To retrieve a specific version, you have to specify its version ID. The following figure shows that a `GET versionId` request retrieves the specified version of the object (not necessarily the current one).

You can retrieve object versions in Amazon S3 using the console, AWS SDKs, or REST API.

Note

To access object versions older than 300 versions, you must use the AWS CLI or the object's URL.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing object properties in the Amazon S3 console](#).

Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

The examples for uploading objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For examples of downloading objects using AWS SDKs for Java, .NET, and PHP, see [Downloading objects](#).

For examples of listing the version of objects using AWS SDKs for .NET and Rust, see [List the version of objects in an Amazon S3 bucket](#).

Using the REST API

To retrieve a specific object version

1. Set `versionId` to the ID of the version of the object that you want to retrieve.
2. Send a `GET Object versionId` request.

Example — Retrieving a versioned object

The following request retrieves version L4kqtJlcpXroDTDmpUMLUo of my-image.jpg.

```
GET /my-image.jpg?versionId=L4kqtJlcpXroDTDmpUMLUo HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

You can retrieve just the metadata of an object (not the content). For information, see [the section called “Retrieving version metadata”](#).

For information about restoring a previous object version, see [the section called “Restoring previous versions”](#).

Retrieving the metadata of an object version

If you only want to retrieve the metadata of an object (and not its content), you use the HEAD operation. By default, you get the metadata of the most recent version. To retrieve the metadata of a specific object version, you specify its version ID.

To retrieve the metadata of an object version

1. Set `versionId` to the ID of the version of the object whose metadata you want to retrieve.
2. Send a `HEAD Object versionId` request.

Example — Retrieving the metadata of a versioned object

The following request retrieves the metadata of version 3HL4kqCxf3vjVBH40NrjfkD of my-image.jpg.

```
HEAD /my-image.jpg?versionId=3HL4kqCxf3vjVBH40NrjfkD HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

The following shows a sample response.

```
HTTP/1.1 200 OK
```

```
x-amz-id-2: ef8yU9AS1ed40pIszj7UDNEHGran
x-amz-request-id: 318BC8BC143432E5
x-amz-version-id: 3HL4kqtJlcpXroDTDmjVBH40Nrjfkd
Date: Wed, 28 Oct 2009 22:32:00 GMT
Last-Modified: Sun, 1 Jan 2006 12:00:00 GMT
ETag: "fba9dede5f27731c9771645a39863328"
Content-Length: 434234
Content-Type: text/plain
Connection: close
Server: AmazonS3
```

Restoring previous versions

You can use versioning to retrieve previous versions of an object. There are two approaches to doing so:

- Copy a previous version of the object into the same bucket.

The copied object becomes the current version of that object and all object versions are preserved.

- Permanently delete the current version of the object.

When you delete the current object version, you, in effect, turn the previous version into the current version of that object.

Because all object versions are preserved, you can make any earlier version the current version by copying a specific version of the object into the same bucket. In the following figure, the source object (ID = 111111) is copied into the same bucket. Amazon S3 supplies a new ID (88778877) and it becomes the current version of the object. So, the bucket has both the original object version (111111) and its copy (88778877). For more information about getting a previous version and then uploading it to make it the current version, see [Retrieving object versions from a versioning-enabled bucket](#) and [Uploading objects](#).

A subsequent GET retrieves version 88778877.

The following figure shows how deleting the current version (121212) of an object leaves the previous version (111111) as the current object. For more information about deleting an object, see [Deleting a single object](#).

A subsequent GET retrieves version 111111.

Note

To restore object versions in batches, you can [use the CopyObject operation](#). The CopyObject operation copies each object that is specified in the manifest. However, be aware that objects aren't necessarily copied in the same order as they appear in the manifest. For versioned buckets, if preserving current/non-current version order

is important, you should copy all non-current versions first. Then, after the first job is complete, copy the current versions in a subsequent job.

To restore previous object versions

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to retrieve.
6. Choose **Actions**, choose **Download**, and save the object.

You also can view, download, and delete object versions in the object overview panel. For more information, see [Viewing object properties in the Amazon S3 console](#).

A Important

You can undelete an object only if it was deleted as the latest (current) version. You can't undelete a previous version of an object that was deleted. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

The following Python code example restores a versioned object's previous version by deleting all versions that occurred after the specified rollback version.

```
def rollback_object(bucket, object_key, version_id):
    """
```

Rolls back an object to an earlier version by deleting all versions that occurred after the specified rollback version.

Usage is shown in the `usage_demo_single_object` function at the end of this module.

```
:param bucket: The bucket that holds the object to roll back.  
:param object_key: The object to roll back.  
:param version_id: The version ID to roll back to.  
"""  
  
# Versions must be sorted by last_modified date because delete markers are  
# at the end of the list even when they are interspersed in time.  
versions = sorted(  
    bucket.object_versions.filter(Prefix=object_key),  
    key=attrgetter("last_modified"),  
    reverse=True,  
)  
  
logger.debug(  
    "Got versions:\n%s",  
    "\n".join(  
        [  
            f"\t{version.version_id}, last modified {version.last_modified}"  
            for version in versions  
        ]  
    ),  
)  
  
if version_id in [ver.version_id for ver in versions]:  
    print(f"Rolling back to version {version_id}")  
    for version in versions:  
        if version.version_id != version_id:  
            version.delete()  
            print(f"Deleted version {version.version_id}")  
        else:  
            break  
  
    print(f"Active version is now {bucket.Object(object_key).version_id}")  
else:  
    raise KeyError(  
        f"{version_id} was not found in the list of versions for "  
        f"{object_key}."  
    )
```

Deleting object versions from a versioning-enabled bucket

You can delete object versions from Amazon S3 buckets whenever you want. You can also define lifecycle configuration rules for objects that have a well-defined lifecycle to request Amazon S3 to expire current object versions or permanently remove noncurrent object versions. When your bucket has versioning enabled or the versioning is suspended, the lifecycle configuration actions work as follows:

- The `Expiration` action applies to the current object version. Instead of deleting the current object version, Amazon S3 retains the current version as a noncurrent version by adding a *delete marker*, which then becomes the current version.
- The `NoncurrentVersionExpiration` action applies to noncurrent object versions, and Amazon S3 permanently removes these object versions. You cannot recover permanently removed objects.

For more information about S3 Lifecycle, see [Managing the lifecycle of objects](#) and [Examples of S3 Lifecycle configurations](#).

To see how many current and noncurrent object versions that your buckets have, you can use Amazon S3 Storage Lens metrics. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. For more information, see [Using S3 Storage Lens to optimize your storage costs](#). For a complete list of metrics, see [S3 Storage Lens metrics glossary](#).

Note

Normal Amazon S3 rates apply for every version of an object that is stored and transferred, including noncurrent object versions. For more information, see [Amazon S3 pricing](#).

Delete request use cases

A DELETE request has the following use cases:

- When versioning is enabled, a simple DELETE cannot permanently delete an object. (A simple DELETE request is a request that doesn't specify a version ID.) Instead, Amazon S3 inserts a

delete marker in the bucket, and that marker becomes the current version of the object with a new ID.

When you try to GET an object whose current version is a delete marker, Amazon S3 behaves as though the object has been deleted (even though it has not been erased) and returns a 404 error. For more information, see [Working with delete markers](#).

The following figure shows that a simple DELETE does not actually remove the specified object. Instead, Amazon S3 inserts a delete marker.

- To delete versioned objects permanently, you must use `DELETE Object versionId`.

The following figure shows that deleting a specified object version permanently removes that object.

To delete object versions

You can delete object versions in Amazon S3 using the console, AWS SDKs, the REST API, or the AWS Command Line Interface.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that contains the object.
3. In the **Objects** list, choose the name of the object.
4. Choose **Versions**.

Amazon S3 shows all the versions for the object.

5. Select the check box next to the **Version ID** for the versions that you want to permanently delete.
6. Choose **Delete**.
7. In **Permanently delete objects?**, enter **permanently delete**.

 **Warning**

When you permanently delete an object version, the action cannot be undone.

8. Choose **Delete objects**.

Amazon S3 deletes the object version.

Using the AWS SDKs

For examples of deleting objects using the AWS SDKs for Java, .NET, and PHP, see [Deleting Amazon S3 objects](#). The examples for deleting objects in nonversioned and versioning-enabled buckets are the same. However, for versioning-enabled buckets, Amazon S3 assigns a version number. Otherwise, the version number is null.

For information about using other AWS SDKs, see the [AWS Developer Center](#).

Python

The following Python code example permanently deletes a versioned object by deleting all of its versions.

```
def permanently_delete_object(bucket, object_key):
    """
    Permanently deletes a versioned object by deleting all of its versions.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

    :param bucket: The bucket that contains the object.
    :param object_key: The object to delete.
    """
    try:
        bucket.object_versions.filter(Prefix=object_key).delete()
        logger.info("Permanently deleted all versions of object %s.", object_key)
    except ClientError:
        logger.exception("Couldn't delete all versions of %s.", object_key)
        raise
```

Using the REST API

To delete a specific version of an object

- In a DELETE, specify a version ID.

Example — Deleting a specific version

The following example deletes version UIORUnfnd89493jJFJ of photo.gif.

```
DELETE /photo.gif?versionId=UIORUnfnd89493jJFJ HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:xQE0diMbLRepdf3YB+FIEXAMPLE=
Content-Type: text/plain
Content-Length: 0
```

Using the AWS CLI

The following command deletes an object named test.txt from a bucket named **amzn-s3-demo-bucket1**. To remove a specific version of an object, you must be the bucket owner and you must use the version Id subresource.

```
aws s3api delete-object --bucket amzn-s3-demo-bucket1 --key test.txt --version-id versionID
```

For more information about `delete-object` see [delete-object](#) in the *AWS CLI Command Reference*.

For more information about deleting object versions, see the following topics:

- [Working with delete markers](#)
- [Removing delete markers to make an older version current](#)
- [Deleting an object from an MFA delete-enabled bucket](#)

Working with delete markers

A *delete marker* in Amazon S3 is a placeholder (or marker) for a versioned object that was specified in a simple DELETE request. A simple DELETE request is a request that doesn't specify a version ID. Because the object is in a versioning-enabled bucket, the object is not deleted. But the delete marker makes Amazon S3 behave as if the object is deleted. You can use an Amazon S3 API DELETE call on a delete marker. To do this, you must make the DELETE request by using an AWS Identity and Access Management (IAM) user or role with the appropriate permissions.

A delete marker has a *key name* (or *key*) and version ID like any other object. However, a delete marker differs from other objects in the following ways:

- A delete marker doesn't have data associated with it.
- A delete marker isn't associated with an access control list (ACL) value.
- If you issue a GET request for a delete marker, the GET request doesn't retrieve anything because a delete marker has no data. Specifically, when your GET request doesn't specify a `versionId`, you get a 404 (Not Found) error.

Delete markers accrue a minimal charge for storage in Amazon S3. The storage size of a delete marker is equal to the size of the key name of the delete marker. A key name is a sequence of

Unicode characters. The UTF-8 encoding for the key name adds 1-4 bytes of storage to your bucket for each character in the name. Delete markers are stored in the S3 Standard storage class.

If you want to find out how many delete markers you have and what storage class they're stored in, you can use Amazon S3 Storage Lens. For more information, see [Assessing your storage activity and usage with Amazon S3 Storage Lens](#) and [Amazon S3 Storage Lens metrics glossary](#).

For more information about key names, see [Naming Amazon S3 objects](#). For information about deleting a delete marker, see [Managing delete markers](#).

Only Amazon S3 can create a delete marker, and it does so whenever you send a `DeleteObject` request on an object in a versioning-enabled or suspended bucket. The object specified in the `DELETE` request is not actually deleted. Instead, the delete marker becomes the current version of the object. The object's key name (or key) becomes the key of the delete marker.

When you get an object without specifying a `versionId` in your request, if its current version is a delete marker, Amazon S3 responds with the following:

- A 404 (Not Found) error
- A response header, `x-amz-delete-marker: true`

When you get an object by specifying a `versionId` in your request, if the specified version is a delete marker, Amazon S3 responds with the following:

- A 405 (Method Not Allowed) error
- A response header, `x-amz-delete-marker: true`
- A response header, `Last-Modified: timestamp` (only when using the [HeadObject](#) or [GetObject](#) API operations)

The `x-amz-delete-marker: true` response header tells you that the object accessed was a delete marker. This response header never returns `false`, because when the value is `false`, the current or specified version of the object is not a delete marker.

The `Last-Modified` response header provides the creation time of the delete markers.

The following figure shows how a `GetObject` API call on an object whose current version is a delete marker responds with a 404 (Not Found) error and the response header includes `x-amz-delete-marker: true`.

If you make a `GetObject` call on an object by specifying a `versionId` in your request, and if the specified version is a delete marker, Amazon S3 responds with a 405 (Method Not Allowed) error and the response headers include `x-amz-delete-marker: true` and `Last-Modified: timestamp`.

The only way to list delete markers (and other versions of an object) is by using the `versions` subresource in a [ListObjectVersions](#) request. The following figure shows that a [ListObjectsV2](#) or [ListObjects](#) request doesn't return objects whose current version is a delete marker.

Managing delete markers

Configuring lifecycle to clean up expired delete markers automatically

An expired object delete marker is one where all object versions are deleted and only a single delete marker remains. If the lifecycle configuration is set to delete current versions, or the `ExpiredObjectDeleteMarker` action is explicitly set, Amazon S3 removes the expired object's delete marker. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

Removing delete markers to make an older version current

When you delete an object in a versioning-enabled bucket, all versions remain in the bucket, and Amazon S3 creates a delete marker for the object. To undelete the object, you must delete this delete marker. For more information about versioning and delete markers, see [Retaining multiple versions of objects with S3 Versioning](#).

To delete a delete marker permanently, you must include its version ID in a `DeleteObject` `versionId` request. The following figure shows how a `DeleteObject` `versionId` request permanently removes a delete marker.

The effect of removing the delete marker is that a simple GET request will now retrieve the current version ID (121212) of the object.

Note

If you use a DeleteObject request where the current version is a delete marker (without specifying the version ID of the delete marker), Amazon S3 does not delete the delete marker, but instead PUTs another delete marker.

To delete a delete marker with a NULL version ID, you must pass the NULL as the version ID in the DeleteObject request. The following figure shows how a simple DeleteObject request made without a version ID where the current version is a delete marker, removes nothing, but instead adds an additional delete marker with a unique version ID (7498372).

Using the S3 console

Use the following steps to recover deleted objects that are not folders from your S3 bucket, including objects that are within those folders.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. To see a list of the **versions** of the objects in the bucket, choose the **List versions** switch. You'll be able to see the delete markers for deleted objects.
4. To undelete an object, you must delete the delete marker. Select the check box next to the **delete marker** of the object to recover, and then choose **Delete**.
5. Confirm the deletion on the **Delete objects** page.
 - a. For **Permanently delete objects?** enter **permanently delete**.
 - b. Choose **Delete objects**.

Note

You can't use the Amazon S3 console to undelete folders. You must use the AWS CLI or SDK. For examples, see [How can I retrieve an Amazon S3 object that was deleted in a versioning-enabled bucket?](#) in the AWS Knowledge Center.

Using the REST API

To permanently remove a delete marker

1. Set `versionId` to the ID of the version to the delete marker you want to remove.
2. Send a `DELETE Object versionId` request.

Example — Removing a delete marker

The following example removes the delete marker for `photo.gif` version 4857693.

```
DELETE /photo.gif?versionId=4857693 HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

When you delete a delete marker, Amazon S3 includes the following in the response.

```
204 NoContent
x-amz-version-id: versionID
x-amz-delete-marker: true
```

Using the AWS SDKs

For information about using other AWS SDKs, see the [AWSDeveloper Center](#).

Python

The following Python code example demonstrates how to remove a delete marker from an object and thus makes the most recent non-current version, the current version of the object.

```
def revive_object(bucket, object_key):
    """
    Revives a versioned object that was deleted by removing the object's active
    delete marker.

    A versioned object presents as deleted when its latest version is a delete
    marker.

    By removing the delete marker, we make the previous version the latest version
    and the object then presents as *not* deleted.

    Usage is shown in the usage_demo_single_object function at the end of this
    module.

```

```
:param bucket: The bucket that contains the object.
:param object_key: The object to revive.
"""
# Get the latest version for the object.
response = s3.meta.client.list_object_versions(
    Bucket=bucket.name, Prefix=object_key, MaxKeys=1
)

if "DeleteMarkers" in response:
    latest_version = response["DeleteMarkers"][0]
    if latest_version["IsLatest"]:
        logger.info(
            "Object %s was indeed deleted on %s. Let's revive it.",
            object_key,
            latest_version["LastModified"],
        )
        obj = bucket.Object(object_key)
        obj.Version(latest_version["VersionId"]).delete()
        logger.info(
            "Revived %s, active version is now %s with body '%s'",
            object_key,
            obj.version_id,
            obj.get()["Body"].read(),
        )
    else:
        logger.warning(
            "Delete marker is not the latest version for %s!", object_key
        )
elif "Versions" in response:
    logger.warning("Got an active version for %s, nothing to do.", object_key)
else:
    logger.error("Couldn't get any version info for %s.", object_key)
```

Deleting an object from an MFA delete-enabled bucket

If a bucket's versioning configuration is MFA delete enabled, the bucket owner must include the `x-amz-mfa` request header in requests to permanently delete an object version or change the versioning state of the bucket. Requests that include `x-amz-mfa` must use HTTPS.

The header's value is the concatenation of your authentication device's serial number, a space, and the authentication code displayed on it. If you don't include this request header, the request fails.

For more information about authentication devices, see [Multi-factor Authentication](#).

Example — Deleting an object from an MFA delete-enabled bucket

The following example deletes my-image.jpg (with the specified version), which is in a bucket configured with MFA delete enabled.

Note the space between **[SerialNumber]** and **[AuthenticationCode]**. For more information, see [DeleteObject](#) in the *Amazon Simple Storage Service API Reference*.

```
DELETE /my-image.jpg?versionId=3HL4kqCxf3vjVBH40Nrjfkd HTTPS/1.1
Host: bucketName.s3.amazonaws.com
x-amz-mfa: 20899872 301749
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
```

For more information about enabling MFA delete, see [Configuring MFA delete](#).

Configuring versioned object permissions

Permissions for objects in Amazon S3 are set at the version level. Each version has its own object owner. The AWS account that creates the object version is the owner. So, you can set different permissions for different versions of the same object. To do so, you must specify the version ID of the object whose permissions you want to set in a PUT Object `versionId acl` request. For a detailed description and instructions on using ACLs, see [Identity and Access Management for Amazon S3](#).

Example — Setting permissions for an object version

The following request sets the permission of the grantee, BucketOwner@amazon.com, to FULL_CONTROL on the key, my-image.jpg, version ID, 3HL4kqtJvjVBH40Nrjfkd.

```
PUT /my-image.jpg?acl&versionId=3HL4kqtJvjVBH40Nrjfkd HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU=
Content-Length: 124

<AccessControlPolicy>

      <ID>a9a7b886d6fd24a52fe8ca5bef65f89a64e0193f23000e241bf9b1c61be666e9</ID>
      <DisplayName>BucketOwner@amazon.com</DisplayName>
    </Grantee>
    <Permission>FULL_CONTROL</Permission>
  </Grant>
</AccessControlList>
</AccessControlPolicy>
```

Likewise, to get the permissions of a specific object version, you must specify its version ID in a GET Object `versionId acl` request. You need to include the version ID because, by default, GET Object `acl` returns the permissions of the current version of the object.

Example — Retrieving the permissions for a specified object version

In the following example, Amazon S3 returns the permissions for the key, `my-image.jpg`, version ID, `DVBH40Nr8X8gUMLUo`.

```
GET /my-image.jpg?versionId=DVBH40Nr8X8gUMLUo&acl HTTP/1.1
Host: bucket.s3.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:0RQf4/cRonhpaBX5sCYVf1bNRuU
```

For more information, see [GetObjectAcl](#) in the *Amazon Simple Storage Service API Reference*.

Working with objects in a versioning-suspended bucket

In Amazon S3, you can suspend versioning to stop accruing new versions of the same object in a bucket. You might do this because you only want a single version of an object in a bucket. Or, you might not want to accrue charges for multiple versions.

When you suspend versioning, existing objects in your bucket do not change. What changes is how Amazon S3 handles objects in future requests. The topics in this section explain various object operations in a versioning-suspended bucket, including adding, retrieving, and deleting objects.

For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#). For more information about retrieving object versions, see [Retrieving object versions from a versioning-enabled bucket](#).

Topics

- [Adding objects to versioning-suspended buckets](#)
- [Retrieving objects from versioning-suspended buckets](#)
- [Deleting objects from versioning-suspended buckets](#)

Adding objects to versioning-suspended buckets

You can add objects to versioning-suspended buckets in Amazon S3 to create the object with a null version ID or overwrite any object version with a matching version ID.

After you suspend versioning on a bucket, Amazon S3 automatically adds a null version ID to every subsequent object stored thereafter (using PUT, POST, or CopyObject) in that bucket.

The following figure shows how Amazon S3 adds the version ID of null to an object when it is added to a version-suspended bucket.

If a null version is already in the bucket and you add another object with the same key, the added object overwrites the original null version.

If there are versioned objects in the bucket, the version you PUT becomes the current version of the object. The following figure shows how adding an object to a bucket that contains versioned objects does not overwrite the object already in the bucket.

In this case, version 111111 was already in the bucket. Amazon S3 attaches a version ID of null to the object being added and stores it in the bucket. Version 111111 is not overwritten.

If a null version already exists in a bucket, the null version is overwritten, as shown in the following figure.

Although the key and version ID (null) of the null version are the same before and after the PUT, the contents of the null version originally stored in the bucket are replaced by the contents of the object PUT into the bucket.

Retrieving objects from versioning-suspended buckets

A GET Object request returns the current version of an object whether you've enabled versioning on a bucket or not. The following figure shows how a simple GET returns the current version of an object.

Deleting objects from versioning-suspended buckets

You can delete objects from versioning-suspended buckets to remove an object with a null version ID.

If versioning is suspended for a bucket, a DELETE request:

- Can only remove an object whose version ID is null.
- Doesn't remove anything if there isn't a null version of the object in the bucket.
- Inserts a delete marker into the bucket.

If bucket versioning is suspended, the operation removes the object that has a null `versionId`. If a version ID exists, Amazon S3 inserts a delete marker that becomes the current version of the object. The following figure shows how a simple DELETE removes a null version and Amazon S3 inserts a delete marker in its place instead with a null version ID.

To permanently delete an object that has a `versionId`, you must include the object's `versionId` in the request. Since a delete marker doesn't contain any content, you'll lose the content for the null version when a delete marker replaces it.

The following figure shows a bucket that doesn't have a null version. In this case, the `DELETE` removes nothing. Instead, Amazon S3 just inserts a delete marker.

Even in a versioning-suspended bucket, the bucket owner can permanently delete a specified version by including the version ID in the `DELETE` request. The following figure shows that deleting a specified object version permanently removes that version of the object. Only the bucket owner can delete a specified object version.

Troubleshooting versioning

The following topics can help you troubleshoot some common Amazon S3 versioning issues.

Topics

- [I want to recover objects that were accidentally deleted in a versioning-enabled bucket](#)
- [I want to permanently delete versioned objects](#)
- [I'm experiencing performance degradation after enabling bucket versioning](#)

I want to recover objects that were accidentally deleted in a versioning-enabled bucket

In general, when object versions are deleted from S3 buckets, there is no way for Amazon S3 to recover them. However, if you have enabled S3 Versioning on your S3 bucket, a DELETE request that doesn't specify a version ID cannot permanently delete an object. Instead, a delete marker is added as a placeholder. This delete marker becomes the current version of the object.

To verify whether your deleted objects are permanently deleted or temporarily deleted (with a delete marker in their place), do the following:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 2. In the left navigation pane, choose **Buckets**.
 3. In the **Buckets** list, choose the name of the bucket that contains the object.
 4. In the **Objects** list, Turn on the **Show versions** toggle to the right of the search bar, and then search for the deleted object in the search bar. This toggle is available only if versioning was previously enabled on the bucket.
- You can also use [S3 Inventory to search for deleted objects](#).
5. If you can't find the object after toggling **Show versions** or creating an inventory report, and you also cannot find a [delete marker](#) of the object, the deletion is permanent and the object cannot be recovered.

You can also verify a deleted object's status by using the HeadObject API operation from the AWS Command Line Interface (AWS CLI). To do so, use the following head-object command and replace the *user input placeholders* with your own information:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html
```

If you run the head-object command on a versioned object whose current version is a delete marker, you will receive a 404 Not Found error. For example:

An error occurred (404) when calling the HeadObject operation: Not Found

If you run the head-object command on a versioned object and provide the object's version ID, Amazon S3 retrieves the object's metadata, confirming that the object still exists and is not permanently deleted.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key index.html --version-id versionID
```

```
{  
  "AcceptRanges": "bytes",  
  "ContentType": "text/html",  
  "LastModified": "Thu, 16 Apr 2015 18:19:14 GMT",  
  "ContentLength": 77,  
  "VersionId": "Zg5HyL7m.eZU9iM7AV1JkrqAiE.0UG4q",  
  "ETag": "\"30a6ec7e1a9ad79c203d05a589c8b400\"",  
  "Metadata": {}  
}
```

If the object is found and the newest version is a delete marker, the previous version of the object still exists. Because the delete marker is the current version of the object, you can recover the object by deleting the delete marker.

After you permanently remove the delete marker, the second newest version of the object becomes the current version of the object, making your object available once again. For a visual depiction of how objects are recovered, see [Removing delete markers](#).

To remove a specific version of an object, you must be the bucket owner. To delete a delete marker permanently, you must include its version ID in a DeleteObject request. To delete the delete marker, use the following command, and replace the *user input placeholders* with your own information:

```
aws s3api delete-object --bucket amzn-s3-demo-bucket --key index.html --version-id versionID
```

For more information about the delete-object command, see [delete-object](#) in the *AWS CLI Command Reference*. For more information about permanently deleting delete markers, see [Managing delete markers](#).

I want to permanently delete versioned objects

In a versioning-enabled bucket, a DELETE request without a version ID cannot permanently delete an object. Instead, such a request inserts a delete marker.

To permanently delete versioned objects, you can choose from the following methods:

- Create an S3 Lifecycle rule to permanently delete noncurrent versions. To permanently delete noncurrent versions, select **Permanently delete noncurrent versions of objects**, and then enter a number under **Days after objects become noncurrent**. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**. For more information about creating this rule, see [Setting an S3 Lifecycle configuration](#).
- Delete a specified version by including the version ID in the DELETE request. For more information, see [How to delete versioned objects permanently](#).
- Create a lifecycle rule to expire current versions. To expire current versions of objects, select **Expire current versions of objects**, and then add a number under **Days after object creation**. For more information about creating this lifecycle rule, see [Setting an S3 Lifecycle configuration](#).
- To permanently delete all versioned objects and delete markers, create two lifecycle rules: one to expire current versions and permanently delete noncurrent versions of objects, and the other to delete expired object delete markers.

In a versioning-enabled bucket, a DELETE request that doesn't specify a version ID can remove only objects with a NULL version ID. If the object was uploaded when versioning was enabled, a DELETE request that doesn't specify a version ID creates a delete marker of that object.

Note

For S3 Object Lock-enabled buckets, a DELETE object request with a protected object version ID causes a 403 Access Denied error. A DELETE object request without a version ID adds a delete marker as the newest version of the object with a 200 OK response. Objects protected by Object Lock cannot be permanently deleted until their retention periods and legal holds are removed. For more information, see [the section called "How S3 Object Lock works"](#).

I'm experiencing performance degradation after enabling bucket versioning

Performance degradation can occur on versioning-enabled buckets if there are too many delete markers or versioned objects, and if best practices aren't followed.

Too many delete markers

After you enable versioning on a bucket, a DELETE request without a version ID made to an object creates a delete marker with a unique version ID. Lifecycle configurations with an **Expire current versions of objects** rule add a delete marker with a unique version ID to every object. Excessive delete markers can reduce performance in the bucket.

When versioning is suspended on a bucket, Amazon S3 marks the version ID as NULL on newly created objects. An expiration action in a versioning-suspended bucket causes Amazon S3 to create a delete marker with NULL as the version ID. In a versioning-suspended bucket, a NULL delete marker is created for any delete request. These NULL delete markers are also called expired object delete markers when all object versions are deleted and only a single delete marker remains. If too many NULL delete markers accumulate, performance degradation in the bucket occurs.

Too many versioned objects

If a versioning-enabled bucket contains objects with millions of versions, an increase in 503 Service Unavailable errors can occur. If you notice a significant increase in the number of HTTP 503 Service Unavailable responses received for PUT or DELETE object requests to a versioning-enabled bucket, you might have one or more objects in the bucket with millions of versions. When you have objects with millions of versions, Amazon S3 automatically throttles requests to the bucket. Throttling requests protects your bucket from an excessive amount of request traffic, which could potentially impede other requests made to the same bucket.

To determine which objects have millions of versions, use S3 Inventory. S3 Inventory generates a report that provides a flat file list of the objects in a bucket. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

To verify if there are high number of versioned objects in the bucket, use S3 Storage Lens metrics to view the **Current version object count**, **Noncurrent version object count**, and **Delete marker object count**. For more information about Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

The Amazon S3 team encourages customers to investigate applications that repeatedly overwrite the same object, potentially creating millions of versions for that object, to determine whether the

application is working as intended. For instance, an application overwriting the same object every minute for a week can create over ten thousand versions. We recommend storing less than one hundred thousand versions for each object. If you have a use case that requires millions of versions for one or more objects, contact the AWS Support team for assistance with determining a better solution.

Best practices

To prevent versioning-related performance degradation issues, we recommend that you employ the following best practices:

- Enable a lifecycle rule to expire the previous versions of objects. For example, you can create a lifecycle rule to expire noncurrent versions after 30 days of the object being noncurrent. You can also retain multiple noncurrent versions if you don't want to delete all of them. For more information, see [Setting an S3 Lifecycle configuration](#).
- Enable a lifecycle rule to delete expired object delete markers that don't have associated data objects in the bucket. For more information, see [Removing expired object delete markers](#).

For additional Amazon S3 performance-optimization best practices, see [Best practices design patterns](#).

Locking objects with Object Lock

S3 Object Lock can help prevent Amazon S3 objects from being deleted or overwritten for a fixed amount of time or indefinitely. Object Lock uses a *write-once-read-many* (WORM) model to store objects. You can use Object Lock to help meet regulatory requirements that require WORM storage, or to add another layer of protection against object changes or deletion.

Note

S3 Object Lock has been assessed by Cohasset Associates for use in environments that are subject to SEC 17a-4, CFTC, and FINRA regulations. For more information about how Object Lock relates to these regulations, see the [Cohasset Associates Compliance Assessment](#).

Object Lock provides two ways to manage object retention: *retention periods* and *legal holds*. An object version can have a retention period, a legal hold, or both.

- **Retention period** – A retention period specifies a fixed period of time during which an object version remains locked. You can set a unique retention period for individual objects. Additionally, you can set a default retention period on an S3 bucket. You may also restrict the minimum and maximum allowable retention periods with the `s3:object-lock-remaining-retention-days` condition key in the bucket policy. This helps you establish a range of retention periods and by restricting retention periods that may be shorter or longer than this range.
- **Legal hold** – A legal hold provides the same protection as a retention period, but it has no expiration date. Instead, a legal hold remains in place until you explicitly remove it. Legal holds are independent from retention periods and are placed on individual object versions.

Object Lock works only in buckets that have S3 Versioning enabled. When you lock an object version, Amazon S3 stores the lock information in the metadata for that object version. Placing a retention period or a legal hold on an object protects only the version that's specified in the request. Retention periods and legal holds don't prevent new versions of the object from being created, or delete markers to be added on top of the object. For information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).

If you put an object into a bucket that already contains an existing protected object with the same object key name, Amazon S3 creates a new version of that object. The existing protected version of the object remains locked according to its retention configuration.

How S3 Object Lock works

Topics

- [Retention periods](#)
- [Retention modes](#)
- [Legal holds](#)
- [Best practices for using S3 Object Lock](#)
- [Required permissions](#)

Retention periods

A *retention period* protects an object version for a fixed amount of time. When you place a retention period on an object version, Amazon S3 stores a timestamp in the object version's metadata to indicate when the retention period expires. After the retention period expires, the object version can be overwritten or deleted.

You can place a retention period explicitly on an individual object version or on a bucket's properties so that it applies to all objects in the bucket automatically. When you apply a retention period to an object version explicitly, you specify a *Retain Until Date* for the object version. Amazon S3 stores this date in the object version's metadata.

You can also set a retention period in a bucket's properties. When you set a retention period on a bucket, you specify a duration, in either days or years, for how long to protect every object version placed in the bucket. When you place an object in the bucket, Amazon S3 calculates a *Retain Until Date* for the object version by adding the specified duration to the object version's creation timestamp. The object version is then protected exactly as though you explicitly placed an individual lock with that retention period on the object version.

Note

When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

Like all other Object Lock settings, retention periods apply to individual object versions. Different versions of a single object can have different retention modes and periods.

For example, suppose that you have an object that is 15 days into a 30-day retention period, and you PUT an object into Amazon S3 with the same name and a 60-day retention period. In this case, your PUT request succeeds, and Amazon S3 creates a new version of the object with a 60-day retention period. The older version maintains its original retention period and becomes deletable in 15 days.

After you've applied a retention setting to an object version, you can extend the retention period. To do this, submit a new Object Lock request for the object version with a *Retain Until Date* that is later than the one currently configured for the object version. Amazon S3 replaces the existing retention period with the new, longer period. Any user with permissions to place an object retention period can extend a retention period for an object version. To set a retention period, you must have the `s3:PutObjectRetention` permission.

When you set a retention period on an object or S3 bucket, you must select one of two retention modes: *compliance* or *governance*.

Retention modes

S3 Object Lock provides two retention modes that apply different levels of protection to your objects:

- Compliance mode
- Governance mode

In *compliance* mode, a protected object version can't be overwritten or deleted by any user, including the root user in your AWS account. When an object is locked in compliance mode, its retention mode can't be changed, and its retention period can't be shortened. Compliance mode helps ensure that an object version can't be overwritten or deleted for the duration of the retention period.

 **Note**

The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

In *governance* mode, users can't overwrite or delete an object version or alter its lock settings unless they have special permissions. With governance mode, you protect objects against being deleted by most users, but you can still grant some users permission to alter the retention settings or delete the objects if necessary. You can also use governance mode to test retention-period settings before creating a compliance-mode retention period.

To override or remove governance-mode retention settings, you must have the `s3:BypassGovernanceRetention` permission and must explicitly include `x-amz-bypass-governance-retention:true` as a request header with any request that requires overriding governance mode.

 **Note**

By default, the Amazon S3 console includes the `x-amz-bypass-governance-retention:true` header. If you try to delete objects protected by *governance* mode and have the `s3:BypassGovernanceRetention` permission, the operation will succeed.

Legal holds

With Object Lock, you can also place a *legal hold* on an object version. Like a retention period, a legal hold prevents an object version from being overwritten or deleted. However, a legal hold doesn't have an associated fixed amount of time and remains in effect until removed. Legal holds can be freely placed and removed by any user who has the `s3:PutObjectLegalHold` permission.

Legal holds are independent from retention periods. Placing a legal hold on an object version doesn't affect the retention mode or retention period for that object version.

For example, suppose that you place a legal hold on an object version and that object version is also protected by a retention period. If the retention period expires, the object doesn't lose its WORM protection. Rather, the legal hold continues to protect the object until an authorized user explicitly removes the legal hold. Similarly, if you remove a legal hold while an object version has a retention period in effect, the object version remains protected until the retention period expires.

Best practices for using S3 Object Lock

Consider using *Governance mode* if you want to protect objects from being deleted by most users during a pre-defined retention period, but at the same time want some users with special permissions to have the flexibility to alter the retention settings or delete the objects.

Consider using *Compliance mode* if you never want any user, including the root user in your AWS account, to be able to delete the objects during a pre-defined retention period. You can use this mode in case you have a requirement to store compliant data.

You can use *Legal Hold* when you are not sure for how long you want your objects to stay immutable. This could be because you have an upcoming external audit of your data and want to keep objects immutable till the audit is complete. Alternately, you may have an ongoing project utilizing a dataset that you want to keep immutable until the project is complete.

Required permissions

Object Lock operations require specific permissions. Depending on the exact operation that you're attempting, you might need any of the following permissions:

- `s3:BypassGovernanceRetention`
- `s3:GetBucketObjectLockConfiguration`
- `s3:GetObjectLegalHold`

- s3:GetObjectRetention
- s3:PutBucketObjectLockConfiguration
- s3:PutObjectLegalHold
- s3:PutObjectRetention

For a complete list of Amazon S3 permissions with descriptions, see [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*.

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

For information about using conditions with permissions, see [Bucket policy examples using condition keys](#).

Object Lock considerations

Amazon S3 Object Lock can help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely.

You can use the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API to view or set Object Lock information. For general information about S3 Object Lock capabilities, see [Locking objects with Object Lock](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs.
For more information, see [the section called "Logging server access"](#).

Topics

- [Permissions for viewing lock information](#)
- [Bypassing governance mode](#)
- [Using Object Lock with S3 Replication](#)

- [Using Object Lock with encryption](#)
- [Using Object Lock with Amazon S3 Inventory](#)
- [Managing S3 Lifecycle policies with Object Lock](#)
- [Managing delete markers with Object Lock](#)
- [Using S3 Storage Lens with Object Lock](#)
- [Uploading objects to an Object Lock enabled bucket](#)
- [Configuring events and notifications](#)
- [Setting limits on retention periods with a bucket policy](#)

Permissions for viewing lock information

You can programmatically view the Object Lock status of an Amazon S3 object version by using the [HeadObject](#) or [GetObject](#) operations. Both operations return the retention mode, retain until date, and legal hold status for the specified object version. Additionally, you can view the Object Lock status for multiple objects in your S3 bucket using S3 Inventory.

To view an object version's retention mode and retention period, you must have the `s3:GetObjectRetention` permission. To view an object version's legal hold status, you must have the `s3:GetObjectLegalHold` permission. To view a bucket's default retention configuration, you must have the `s3:GetBucketObjectLockConfiguration` permission. If you make a request for an Object Lock configuration on a bucket that doesn't have S3 Object Lock enabled, Amazon S3 returns an error.

Bypassing governance mode

If you have the `s3:BypassGovernanceRetention` permission, you can perform operations on object versions that are locked in governance mode as if they were unprotected. These operations include deleting an object version, shortening the retention period, or removing the Object Lock retention period by placing a new `PutObjectRetention` request with empty parameters.

To bypass governance mode, you must explicitly indicate in your request that you want to bypass this mode. To do this, include the `x-amz-bypass-governance-retention:true` header with your `PutObjectRetention` API operation request, or use the equivalent parameter with requests made through the AWS CLI or AWS SDKs. The S3 console automatically applies this header for requests made through the S3 console if you have the `s3:BypassGovernanceRetention` permission.

Note

Bypassing governance mode doesn't affect an object version's legal hold status. If an object version has a legal hold enabled, the legal hold remains and prevents requests to overwrite or delete the object version.

Using Object Lock with S3 Replication

You can use Object Lock with S3 Replication to enable automatic, asynchronous copying of locked objects and their retention metadata, across S3 buckets. This means that for replicated objects, Amazon S3 takes the object lock configuration of the source bucket. In other words, if the source bucket has Object Lock enabled, the destination buckets must also have Object Lock enabled. If an object is directly uploaded to the destination bucket (outside of S3 Replication), it takes the Object Lock set on the destination bucket. When you use replication, objects in a *source bucket* are replicated to one or more *destination buckets*.

To set up replication on a bucket with Object Lock enabled, you can use the S3 console, AWS CLI, Amazon S3 REST API, or AWS SDKs.

Note

To use Object Lock with replication, you must grant two additional permissions on the source S3 bucket in the AWS Identity and Access Management (IAM) role that you use to set up replication. The two additional permissions are `s3:GetObjectRetention` and `s3:GetObjectLegalHold`. If the role has an `s3:Get*` permission statement, that statement satisfies the requirement. For more information, see [Setting up permissions for live replication](#).

For general information about S3 Replication, see [Replicating objects within and across Regions](#).

For examples of setting up S3 Replication, see [Examples for configuring live replication](#).

Using Object Lock with encryption

Amazon S3 encrypts all new objects by default. You can use Object Lock with your encrypted objects. For more information, see [Protecting data with encryption](#).

While Object Lock can help prevent Amazon S3 objects from being deleted or overwritten, it does not protect against losing access to the encryption keys or encryption keys being deleted. For example, if you encrypt your objects with AWS KMS server-side encryption and your AWS KMS key is deleted your objects may become unreadable.

Using Object Lock with Amazon S3 Inventory

You can configure Amazon S3 Inventory to create lists of the objects in an S3 bucket on a defined schedule. You can configure Amazon S3 Inventory to include the following Object Lock metadata for your objects:

- The retain until date
- The retention mode
- The legal hold status

For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

Managing S3 Lifecycle policies with Object Lock

Object lifecycle management configurations continue to function normally on protected objects, including placing delete markers. However, a locked version of an object cannot be deleted by a S3 Lifecycle expiration policy. Object Lock is maintained regardless of which storage class the object resides in and throughout S3 Lifecycle transitions between storage classes.

For more information about managing object lifecycles, see [Managing the lifecycle of objects](#).

Managing delete markers with Object Lock

Although you can't delete a protected object version, you can still create a delete marker for that object. Placing a delete marker on an object doesn't delete the object or its object versions. However, it makes Amazon S3 behave in most ways as though the object has been deleted. For more information, see [Working with delete markers](#).

Note

Delete markers are not WORM-protected, regardless of any retention period or legal hold in place on the underlying object.

Using S3 Storage Lens with Object Lock

To see metrics for Object Lock-enabled storage bytes and object count, you can use Amazon S3 Storage Lens. S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity.

For more information, see [Using S3 Storage Lens to protect your data](#).

For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Uploading objects to an Object Lock enabled bucket

The Content-MD5 or x-amz-sdk-checksum-algorithm header is required for any request to upload an object with a retention period configured using Object Lock. These headers are a way to verify the integrity of your object during upload.

When uploading an object with the Amazon S3 console, S3 automatically adds the Content-MD5 header. You can optionally specify an additional checksum function and checksum value through the console as the x-amz-sdk-checksum-algorithm header. If you use the [PutObject](#) API you must specify the Content-MD5 header, the x-amz-sdk-checksum-algorithm header, or both to configure the Object Lock retention period.

For more information, see [Checking object integrity in Amazon S3](#).

Configuring events and notifications

You can use Amazon S3 Event Notifications to track access and changes to your Object Lock configurations and data by using AWS CloudTrail. For information about CloudTrail, see [What is AWS CloudTrail?](#) in the *AWS CloudTrail User Guide*.

You can also use Amazon CloudWatch to generate alerts based on this data. For information about CloudWatch, see the [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

Setting limits on retention periods with a bucket policy

You can set minimum and maximum allowable retention periods for a bucket by using a bucket policy. The maximum retention period is 100 years.

The following example shows a bucket policy that uses the s3:object-lock-remaining-retention-days condition key to set a maximum retention period of 10 days.

```
{  
    "Version": "2012-10-17",  
    "Id": "SetRetentionLimits",  
    "Statement": [  
        {  
            "Sid": "SetRetentionPeriod",  
            "Effect": "Deny",  
            "Principal": "*",  
            "Action": [  
                "s3:PutObjectRetention"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
            "Condition": {  
                "NumericGreaterThan": {  
                    "s3:object-lock-remaining-retention-days": "10"  
                }  
            }  
        }  
    ]  
}
```

Note

If your bucket is the destination bucket for a replication configuration, you can set up minimum and maximum allowable retention periods for object replicas that are created by using replication. To do so, you must allow the `s3:ReplicateObject` action in your bucket policy. For more information about replication permissions, see [the section called “Setting up permissions”](#).

For more information about bucket policies, see the following topics:

- [Actions, resources, and condition keys for Amazon S3 in the Service Authorization Reference](#)

For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).

- [Object operations](#)
- [Bucket policy examples using condition keys](#)

Configuring S3 Object Lock

With Amazon S3 Object Lock, you can store objects in Amazon S3 general purpose buckets by using a *write-once-read-many* (WORM) model. You can use S3 Object Lock to prevent an object from being deleted or overwritten for a fixed amount of time or indefinitely. For general information about Object Lock capabilities, see [Locking objects with Object Lock](#).

Before you lock any objects, you must enable S3 Versioning and Object Lock on a general purpose bucket. Afterward, you can set a retention period, a legal hold, or both.

To work with Object Lock, you must have certain permissions. For a list of the permissions related to various Object Lock operations, see [the section called “Required permissions”](#).

Important

- After you enable Object Lock on a bucket, you can't disable Object Lock or suspend versioning for that bucket.
- S3 buckets with Object Lock can't be used as destination buckets for server access logs. For more information, see [the section called “Logging server access”](#).

Topics

- [Enable Object Lock when creating a new S3 general purpose bucket](#)
- [Enable Object Lock on an existing S3 bucket](#)
- [Set or modify a legal hold on an S3 object](#)
- [Set or modify a retention period on an S3 object](#)
- [Set or modify a default retention period on an S3 bucket](#)

Enable Object Lock when creating a new S3 general purpose bucket

You can enable Object Lock when creating a new S3 general purpose bucket by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **General purpose buckets**.
3. Choose **Create bucket**.

The **Create bucket** page opens.

4. For **Bucket name**, enter a name for your bucket.

 **Note**

After you create a bucket, you can't change its name. For more information about naming buckets, see [General purpose bucket naming rules](#).

5. For **Region**, choose the AWS Region where you want the bucket to reside.
6. Under **Object Ownership**, choose to disable or enable access control lists (ACLs) and control ownership of objects uploaded in your bucket.
7. Under **Block Public Access settings for this bucket**, choose the Block Public Access settings that you want to apply to the bucket.
8. Under **Bucket Versioning**, choose **Enabled**.

Object Lock works only with versioned buckets.

9. (Optional) Under **Tags**, you can choose to add tags to your bucket. Tags are key-value pairs that are used to categorize storage and allocate costs.
10. Under **Advanced settings**, find **Object Lock** and choose **Enable**.

You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.

11. Choose **Create bucket**.

Using the AWS CLI

The following `create-bucket` example creates a new S3 bucket named `amzn-s3-demo-bucket1` with Object Lock enabled:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket1 --object-lock-enabled-for-bucket
```

For more information and examples, see [create-bucket](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to create a new S3 bucket with Object Lock enabled. For more information, see [CreateBucket](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock when creating a new S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Enable Object Lock on an existing S3 bucket

You can enable Object Lock for an existing S3 bucket by using the Amazon S3 console, the AWS CLI, AWS SDKs, or Amazon S3 REST API.

Using the S3 console

Note

Object Lock works only with versioned buckets.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Buckets**.
 3. In the **Buckets** list, choose the name of the bucket that you want to enable Object Lock on.
 4. Choose the **Properties** tab.
 5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
 6. Under **Object Lock**, choose **Enable**.
- You must acknowledge that enabling Object Lock will permanently allow objects in this bucket to be locked.
7. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on a bucket named `amzn-s3-demo-bucket1`:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the Amazon S3 REST API to enable Object Lock on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to enable Object Lock for an existing S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current Object Lock configuration with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a legal hold on an S3 object

You can set or remove a legal hold on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a legal hold on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.

For more information, see [the section called “Legal holds”](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a legal hold on.
4. In the **Objects** list, select the object that you want to set or modify a legal hold on.

5. On the **Object properties** page, find the **Object Lock legal hold** section, and choose **Edit**.
6. Choose **Enable** to set a legal hold or **Disable** to remove a legal hold.
7. Choose **Save changes**.

Using the AWS CLI

The following put-object-legal-hold example sets a legal hold on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
legal-hold="Status=ON"
```

The following put-object-legal-hold example removes a legal hold on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1*:

```
aws s3api put-object-legal-hold --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
legal-hold="Status=OFF"
```

For more information and examples, see [put-object-legal-hold](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set or modify a legal hold on an object. For more information, see [PutObjectLegalHold](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a legal hold on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the current legal hold status with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a retention period on an S3 object

You can set or modify a retention period on an S3 object by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API.

Important

- If you want to set a retention period on an object, the object's bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the object that you want to set or modify a retention period on.
4. In the **Objects** list, select the object that you want to set or modify a retention period on.
5. On the **Object properties** page, find the **Object Lock retention** section, and choose **Edit**.
6. Under **Retention**, choose **Enable** to set a retention period or **Disable** to remove a retention period.

7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Retain until date**, choose the date that you want to have the retention period end on. During this period, your object is WORM-protected and can't be overwritten or deleted. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following put-object-retention example sets a retention period on the object *my-image.fs* in the bucket named *amzn-s3-demo-bucket1* until January 1, 2025:

```
aws s3api put-object-retention --bucket amzn-s3-demo-bucket1 --key my-image.fs --  
retention='{"Mode": "GOVERNANCE", "RetainUntilDate": "2025-01-01T00:00:00"}'
```

For more information and examples, see [put-object-retention](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a retention period on an object. For more information, see [PutObjectRetention](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a retention period on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For examples of how to get the retention period on an object with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Set or modify a default retention period on an S3 bucket

You can set or modify a default retention period on an S3 bucket by using the Amazon S3 console, AWS CLI, AWS SDKs, or Amazon S3 REST API. You specify a duration, in either days or years, for how long to protect every object version placed in the bucket.

Important

- If you want to set a default retention period on a bucket, the bucket must already have Object Lock enabled.
- When you PUT an object version that has an explicit individual retention mode and period in a bucket, the object version's individual Object Lock settings override any bucket property retention settings.
- The only way to delete an object under the compliance mode before its retention date expires is to delete the associated AWS account.

For more information, see [Retention periods](#).

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you want to set or modify a default retention period on.
4. Choose the **Properties** tab.
5. Under **Properties**, scroll down to the **Object Lock** section, and choose **Edit**.
6. Under **Default retention**, choose **Enable** to set a default retention or **Disable** to remove a default retention.

7. If you chose **Enable**, under **Retention mode**, choose either **Governance mode** or **Compliance mode**. For more information, see [Retention modes](#).
8. Under **Default retention period**, choose the number of days or years that you want the retention period to last for. Objects placed in this bucket will be locked for this number of days or years. For more information, see [Retention periods](#).
9. Choose **Save changes**.

Using the AWS CLI

The following `put-object-lock-configuration` example command sets a 50-day Object Lock retention period on the bucket named `amzn-s3-demo-bucket1` by using compliance mode:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled", "Rule": {"DefaultRetention": {"Mode": "COMPLIANCE", "Days": 50 }}}'
```

The following `put-object-lock-configuration` example removes the default retention configuration on a bucket:

```
aws s3api put-object-lock-configuration --bucket amzn-s3-demo-bucket1 --object-lock-configuration='{"ObjectLockEnabled": "Enabled"}'
```

For more information and examples, see [put-object-lock-configuration](#) in the *AWS CLI Command Reference*.

Note

You can run AWS CLI commands from the console by using AWS CloudShell. AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. For more information, see [What is CloudShell?](#) in the *AWS CloudShell User Guide*.

Using the REST API

You can use the REST API to set a default retention period on an existing S3 bucket. For more information, see [PutObjectLockConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to set a default retention period on an existing S3 bucket with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For an interactive scenario demonstrating different Object Lock features using the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

For general information about using different AWS SDKs, see [Developing with Amazon S3 using the AWS SDKs](#) in the *Amazon S3 API Reference*.

Backing up your Amazon S3 data

Amazon S3 is natively integrated with AWS Backup, a fully managed, policy-based service that you can use to centrally define backup policies to protect your data in Amazon S3. After you define your backup policies and assign Amazon S3 resources to the policies, AWS Backup automates the creation of Amazon S3 backups and securely stores the backups in an encrypted backup vault that you designate in your backup plan.

When using AWS Backup for Amazon S3, you can perform the following actions:

- Create continuous backups and periodic backups. Continuous backups are useful for point-in-time restore, and periodic backups are useful to meet your long-term data-retention needs.
- Automate backup scheduling and retention by centrally configuring backup policies.
- Restore backups of Amazon S3 data to a point in time that you specify.

Along with AWS Backup, you can use S3 Versioning and S3 Replication to help recover from accidental deletions and perform your own self-recovery operations.

Prerequisites

You must activate [S3 Versioning](#) on your bucket before AWS Backup can back it up.

Note

We recommend that you [set a lifecycle expiration rule for versioning-enabled buckets](#) that are being backed up. If you do not set a lifecycle expiration period, your Amazon S3 storage costs might increase because AWS Backup retains all versions of your Amazon S3 data.

Getting started

To get started with AWS Backup for Amazon S3, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Restrictions and limitations

To learn about the limitations, see [Creating Amazon S3 backups](#) in the *AWS Backup Developer Guide*.

Cost optimization

Amazon S3 offers a range of features and storage classes to help you optimize costs throughout your data lifecycle. Storage classes offer the flexibility to manage your costs, by providing different data-access levels at corresponding costs, with no upfront fees or commitment to how much content you store. Like other AWS services, you pay as you go and pay only for what you use.

Amazon S3 storage classes are purpose-built to provide the lowest cost storage for different access patterns. These include:

- S3 Standard for general-purpose storage of frequently accessed data.
- Amazon S3 Express One Zone for high-performance frequently accessed data in a single-Availability Zone.
- S3 Intelligent-Tiering to automatically optimize costs for data with unknown or changing access patterns.
- S3 Standard-IA (S3 Standard-IA) and S3 One Zone-IA (S3 One Zone-IA) for long-lived, but less frequently accessed data.
- S3 Glacier Instant Retrieval for archive data that needs immediate access.
- S3 Glacier for archive data that doesn't require immediate access but needs the flexibility to retrieve large sets of data at no cost.
- S3 Glacier Deep Archive for long-term archive and digital preservation at the lowest storage costs in the cloud.

You can move objects to the most cost-effective storage class at any time. Additionally, Amazon S3 provides features to manage your data lifecycle. For example, you can use S3 Lifecycle configuration to automate transitioning objects to more cost-effective storage classes, or to automatically delete expired objects based on the rules that you define.

Features such as S3 Storage Class Analysis, cost allocation tagging, and billing and usage reports help you analyze your cost and usage patterns.

Topics

- [Billing and usage reporting for Amazon S3](#)
- [Understanding and managing Amazon S3 storage classes](#)
- [Managing the lifecycle of objects](#)

Billing and usage reporting for Amazon S3

When using Amazon S3, you don't have to pay any upfront fees or commit to how much content you'll store. Like other AWS services, you pay as you go and pay only for what you use.

AWS provides the following reports for Amazon S3:

- **Billing reports** – Multiple reports that provide high-level views of all of the activity for the AWS services that you're using, including Amazon S3. AWS always bills the owner of the S3 bucket for Amazon S3 fees, unless the bucket was created as a Requester Pays bucket. For more information about Requester Pays, see [Using Requester Pays buckets for storage transfers and usage](#). For more information about billing reports, see [AWS Billing reports for Amazon S3](#).
- **Usage report** – A summary of activity for a specific service, aggregated by hour, day, or month. You can choose which usage type and operation to include. You can also choose how the data is aggregated. For more information, see [AWS usage reports for Amazon S3](#).

The following topics provide information about billing and usage reporting for Amazon S3.

Topics

- [Using cost allocation S3 bucket tags](#)
- [AWS Billing reports for Amazon S3](#)
- [AWS usage reports for Amazon S3](#)
- [Understanding your AWS billing and usage reports for Amazon S3](#)
- [Billing for Amazon S3 error responses](#)

Using cost allocation S3 bucket tags

To track the storage cost or other criteria for individual projects or groups of projects, label your Amazon S3 buckets using cost allocation tags. A *cost allocation tag* is a key-value pair that you associate with an S3 bucket. After you activate cost allocation tags, AWS uses the tags to organize your resource costs on your cost allocation report. Cost allocation tags can only be used to label buckets. For information about tags used for labeling objects, see [Categorizing your storage using tags](#).

The *cost allocation report* lists the AWS usage for your account by product category and linked account user. The report contains the same line items as the detailed billing report (see

[Understanding your AWS billing and usage reports for Amazon S3](#)) and additional columns for your tag keys.

AWS provides two types of cost allocation tags, an AWS-generated tag and user-defined tags. AWS defines, creates, and applies the AWS-generated `createdBy` tag for you after an Amazon S3 `CreateBucket` event. You define, create, and apply *user-defined* tags to your S3 bucket.

You must activate both types of tags separately in the Billing and Cost Management console before they can appear in your billing reports. For more information about AWS-generated tags, see [AWS-Generated Cost Allocation Tags](#).

- To create tags in the console, see [Viewing the properties for an S3 bucket](#).
- To create tags using the Amazon S3 API, see [PUT Bucket tagging](#) in the *Amazon Simple Storage Service API Reference*.
- To create tags using the AWS CLI, see [put-bucket-tagging](#) in the AWS CLI Command Reference.
- For more information about activating tags, see [Using cost allocation tags](#) in the *AWS Billing User Guide*.

User-defined cost allocation tags

A user-defined cost allocation tag has the following components:

- The tag key. The tag key is the name of the tag. For example, in the tag `project/Trinity`, `project` is the key. The tag key is a case-sensitive string that can contain 1 to 128 Unicode characters.
- The tag value. The tag value is a required string. For example, in the tag `project/Trinity`, `Trinity` is the value. The tag value is a case-sensitive string that can contain from 0 to 256 Unicode characters.

For details on the allowed characters for user-defined tags and other restrictions, see [User-Defined Tag Restrictions](#) in the *AWS Billing User Guide*. For more information about user-defined tags, see [User-Defined Cost Allocation Tags](#) in the *AWS Billing User Guide*.

S3 bucket tags

Each S3 bucket has a tag set. A *tag set* contains all of the tags that are assigned to that bucket. A tag set can contain as many as 50 tags, or it can be empty. Keys must be unique within a tag set,

but values in a tag set don't have to be unique. For example, you can have the same value in tag sets named project/Trinity and cost-center/Trinity.

Within a bucket, if you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS doesn't apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, edit, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

AWS Billing reports for Amazon S3

Your monthly bill from AWS separates your usage information and cost by AWS service and function. There are several AWS Billing reports available: the monthly report, the cost allocation report, and detailed billing reports. For information about how to see your billing reports, see [Viewing Your Bill](#) in the *AWS Billing User Guide*.

To track your AWS usage and provide estimated charges associated with your account, you can set up AWS Cost and Usage Reports. For more information, see [What are AWS Cost and Usage Reports?](#) in the *AWS Data Exports Guide*.

You can also download a usage report that gives more detail about your Amazon S3 storage usage than the billing reports. For more information, see [AWS usage reports for Amazon S3](#).

The following table lists the charges associated with Amazon S3 usage.

Charge	Comments
Storage	You pay for storing objects in your S3 buckets. The rate you're charged depends on your objects' size, how long you stored the objects

Charge	Comments
	<p>during the month, and the storage class. Amazon S3 offers the following storage classes: S3 Standard, S3 Express One Zone, S3 Intelligent-Tiering, S3 Standard-IA (IA for infrequent access), S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, S3 Glacier Deep Archive, or Reduced Redundancy Storage (RRS). For more information about storage classes, see Understanding and managing Amazon S3 storage classes.</p> <p>Be aware that if you have S3 Versioning enabled, you're charged for each version of an object that is retained. For more information about versioning, see How S3 Versioning works.</p>
General purpose buckets	You're not billed for the first 2000 general purpose buckets that you create in your account. However, there is a per-bucket rate for each bucket that you create beyond the first 2000. This rate is billed per bucket/month. For information about general purpose bucket pricing, see Amazon S3 Pricing .
Monitoring and automation	You pay a monthly monitoring and automation fee per object stored in the S3 Intelligent-Tiering storage class to monitor access patterns and move objects between access tiers in S3 Intelligent-Tiering.

Charge	Comments
Requests	You pay for requests, for example, GET requests, made against your S3 buckets and objects. This includes lifecycle requests. The rates for requests depend on what kind of request you're making. For information about request pricing, see Amazon S3 Pricing .
Retrievals	You pay for retrieving objects that are stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive storage.
Early deletes	If you delete an object stored in S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage before the minimum storage commitment has passed, you pay an early deletion fee for that object.
Storage management	You pay for the storage management features (Amazon S3 Inventory, analytics, and object tagging) that are enabled on your account's buckets.

Charge	Comments
Bandwidth	<p>You pay for all bandwidth into and out of Amazon S3, except for the following:</p> <ul style="list-style-type: none">• Data transferred in from the internet• Data transferred out to an Amazon Elastic Compute Cloud (Amazon EC2) instance, when the instance is in the same AWS Region as the S3 bucket• Data transferred out to Amazon CloudFront (CloudFront) <p>You also pay a fee for any data transferred by using Amazon S3 Transfer Acceleration.</p>

For detailed information about Amazon S3 usage charges for storage, data transfer, and services, see [Amazon S3 Pricing](#) and the [Amazon S3 FAQs](#).

For information about understanding the codes and abbreviations used in the billing and usage reports for Amazon S3, see [Understanding your AWS billing and usage reports for Amazon S3](#).

- [Amazon S3 Pricing](#)

AWS usage reports for Amazon S3

When you download a usage report, you can choose to aggregate usage data by hour, day, or month. The Amazon S3 usage report lists operations by usage type and AWS Region. For more

detailed reports about your Amazon S3 storage usage, download dynamically generated AWS usage reports. You can choose which usage type, operation, and time period to include. You can also choose how the data is aggregated. For more information about usage reports, see [AWS Usage Report](#)in the *AWS Data Exports User Guide*.

The Amazon S3 usage report includes the following information:

- **Service** – Amazon S3
- **Operation** – The operation performed on your bucket or object. For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).
- **UsageType** – One of the following values:
 - A code that identifies the type of storage
 - A code that identifies the type of request
 - A code that identifies the type of retrieval
 - A code that identifies the type of data transfer
 - A code that identifies early deletions from S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-Infrequent Access (S3 One Zone-IA), S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage
 - **StorageObjectCount** – The count of objects stored within a given bucket

For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).

- **Resource** – The name of the bucket associated with the listed usage.
- **StartTime** – Start time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **EndTime** – End time of the day that the usage applies to, in Coordinated Universal Time (UTC).
- **UsageValue** – One of the following volume values. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.
 - The number of requests during the specified time period
 - The amount of data transferred
 - The amount of data stored in a given hour
 - The amount of data associated with restorations from S3 Standard-IA, S3 One Zone-IA, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage

Tip

For detailed information about every request that Amazon S3 receives for your objects, turn on server access logging for your buckets. For more information, see [Logging requests with server access logging](#).

You can download a usage report as an XML or a comma-separated values (CSV) file. The following is an example CSV usage report opened in a spreadsheet application.

Service	Operation	UsageType	Resource	StartTime	EndTime	UsageValue
AmazonS3	HeadBucket	USW2-C3DataTransfer-Out-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	15309
AmazonS3	PutObject	USW2-C3DataTransfer-In-Bytes	admin-created3	6/1/2017 0:00	7/1/2017 0:00	19062
AmazonS3	HeadBucket	USW2-Requests-Tier2	admin-created3	6/1/2017 0:00	7/1/2017 0:00	68
AmazonS3	PutObjectForRepl	USW1-Requests-SIA-Tier1	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	178294
AmazonS3	PutObjectForRepl	USW1-USW2-AWS-In-Bytes	ca-example-bucket	6/1/2017 0:00	7/1/2017 0:00	387929083

For more information, see [Understanding your AWS billing and usage reports for Amazon S3](#).

Downloading the AWS Usage Report

You can download a usage report as an XML or a CSV file.

To download the usage report

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the title bar, choose your username or account ID, and then choose **Billing and Cost Management**.
3. In the navigation pane, choose **Legacy Pages** and choose **Cost and usage reports**.
4. Under AWS Usage Report, choose **Create a Usage Report**.
5. On the **Download usage report** page, choose the following settings:
 - **Services** – Choose **Amazon Simple Storage Service**.
 - **Usage Types** – For a detailed explanation of Amazon S3 usage types, see [Understanding your AWS billing and usage reports for Amazon S3](#).
 - **Operation** – For a detailed explanation of Amazon S3 operations, see [Tracking Operations in Your Usage Reports](#).

- **Time Period** – The time period that you want the report to cover.
 - **Report Granularity** – Whether you want the report to include subtotals by the hour, by the day, or by the month.
6. Choose **Download**, choose the download format (**XML Report** or **CSV Report**), and then follow the prompts to open or save the report.

Understanding your AWS billing and usage reports for Amazon S3

Amazon S3 billing and usage reports use codes and abbreviations. For usage types in the table that follows, replace *region*, *region1*, and *region2* with abbreviations from this list:

- **APE1:** Asia Pacific (Hong Kong)
- **APN1:** Asia Pacific (Tokyo)
- **APN2:** Asia Pacific (Seoul)
- **APN3:** Asia Pacific (Osaka)
- **APS1:** Asia Pacific (Singapore)
- **APS2:** Asia Pacific (Sydney)
- **APS3:** Asia Pacific (Mumbai)
- **APS4:** Asia Pacific (Jakarta)
- **APS5:** Asia Pacific (Hyderabad)
- **APS6:** Asia Pacific (Melbourne)
- **APS7:** Asia Pacific (Malaysia)
- **APS9:** Asia Pacific (Thailand)
- **CAN1:** Canada (Central)
- **CAN2:** Canada West (Calgary)
- **CNN1:** China (Beijing)
- **CNW1:** China (Ningxia)

- **AFS1:** Africa (Cape Town)
- **EUC2:** Europe (Zurich)
- **EUN1:** Europe (Stockholm)
- **EUS2:** Europe (Spain)
- **EUC1:** Europe (Frankfurt)
- **EU:** Europe (Ireland)
- **EUS1:** Europe (Milan)
- **EUW2:** Europe (London)
- **EUW3:** Europe (Paris)
- **ILC1:** Israel (Tel Aviv)
- **MEC1:** Middle East (UAE)
- **MES1:** Middle East (Bahrain)
- **MXC1:** Mexico (Central)
- **SAE1:** South America (São Paulo)
- **UGW1:** AWS GovCloud (US-West)
- **UGE1:** AWS GovCloud (US-East)
- **USE1 (or no prefix):** US East (N. Virginia)
- **USE2:** US East (Ohio)
- **USW1:** US West (N. California)
- **USW2:** US West (Oregon)

For S3 Multi-Region Access Points usage types in the table that follows, replace *regiongroup1* and *regiongroup2* with abbreviations from this list:

- **AP:** Asia Pacific
- **AU:** Australia
- **EU:** Europe
- **IN:** India
- **NA:** North America
- **SA:** South America

Region groups are geographical groupings of several AWS Regions. For more information, see [Regions and Availability Zones](#). For information about pricing by AWS Region, see [Amazon S3 Pricing](#).

The first column in the following table lists usage types that appear in your billing and usage reports. The typical unit of measurement for data is gigabytes (GB). However, depending on the service and the report, terabytes (TB) might appear instead.

Usage Type	Units	Granularity	Description
<i>region1-region2-AWS-In-A Bytes</i>	GB	Hourly	The amount of accelerated data transferred to <i>region1</i> from <i>region2</i>
<i>region1-region2-AWS-In-A Bytes-T1</i>	GB	Hourly	The amount of T1 accelerated data transferred to <i>region1</i> from <i>region2</i> , where T1 refers to CloudFront requests to points of presence (POPs) in the United States, Europe, and Japan
<i>region1-region2-AWS-In-A Bytes-T2</i>	GB	Hourly	The amount of T2 accelerated data transferred to <i>region1</i> from <i>region2</i> , where T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1-region2-AWS-In-Bytes</i>	GB	Hourly	The amount of data transferred to <i>region1</i> from <i>region2</i>

Usage Type	Units	Granularity	Description
<i>region1-region2-AWS-Out-ABytes</i>	GB	Hourly	The amount of accelerated data transferred from <i>region1</i> to <i>region2</i>
<i>region1-region2-AWS-Out-ABytes-T1</i>	GB	Hourly	The amount of T1 accelerated data transferred from <i>region1</i> to <i>region2</i> , where T1 refers to CloudFront requests to POPs in the United States, Europe, and Japan
<i>region1-region2-AWS-Out-ABytes-T2</i>	GB	Hourly	The amount of T2 accelerated data transferred from <i>region1</i> to <i>region2</i> , where T2 refers to CloudFront requests to POPs in all other AWS edge locations
<i>region1-region2-AWS-Out-Bytes</i>	GB	Hourly	The amount of data transferred from <i>region1</i> to <i>region2</i>
<i>region-BatchOperations-Jobs</i>	Count	Hourly	The number of S3 Batch Operations jobs performed
<i>region-BatchOperations-Objects</i>	Count	Hourly	The number of object operations performed by S3 Batch Operations

Usage Type	Units	Granularity	Description
<i>region</i> -Bulk-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Bulk S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -BytesDeleted-GDA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Deep Archive storage
<i>region</i> -BytesDeleted-GIR	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -BytesDeleted-GLACIER	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -BytesDeleted-INT	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -BytesDeleted-RRS	GB	Monthly	The amount of data deleted by a DeleteObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -BytesDeleted-SIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard-IA storage
<i>region</i> -BytesDeleted-STANDARD	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 Standard storage
<i>region</i> -BytesDeleted-ZIA	GB	Monthly	The amount of data deleted by a DeleteObject operation from S3 One Zone-IA storage
<i>region</i> -C3DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from Amazon EC2 within the same AWS Region
<i>region</i> -C3DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to Amazon EC2 within the same AWS Region

Usage Type	Units	Granularity	Description
<i>region</i> -CloudFront-In-Bytes	GB	Hourly	The amount of data transferred into an AWS Region from a CloudFront distribution
<i>region</i> -CloudFront-Out-Bytes	GB	Hourly	The amount of data transferred from an AWS Region to a CloudFront distribution
<i>region</i> -DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 from the internet
<i>region</i> -DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to the internet ¹
<i>region</i> -DataTransfer-Regional-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to AWS resources within the same AWS Region
<i>region</i> -EarlyDelete-ByteHrs	GB-Hours	Hourly	Prorated storage usage for objects deleted from, S3 Glacier Flexible Retrieval storage before the 90-day minimum commitment ended ²

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-GDA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Deep Archive storage before the 180-day minimum commitment ended ²
<i>region</i> -EarlyDelete-GIR	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-GIR-SmallObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Glacier Instant Retrieval before the 90-day minimum commitment ended.
<i>region</i> -EarlyDelete-SIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 Standard-IA before the 30-day minimum commitment ended ³

Usage Type	Units	Granularity	Description
<i>region</i> -EarlyDelete-SIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 Standard-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA	GB-Hours	Hourly	Prorated storage usage for objects deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -EarlyDelete-ZIA-SmObjects	GB-Hours	Hourly	Prorated storage usage for small objects (smaller than 128 KB) that were deleted from S3 One Zone-IA before the 30-day minimum commitment ended ³
<i>region</i> -Expedited-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with Expedited S3 Glacier Flexible Retrieval requests
Global-Bucket-Hrs-FreeTier	Bucket	Monthly	The number of general purpose buckets in your account within the 2000 bucket account-level free tier

Usage Type	Units	Granularity	Description
Global-Bucket-Hrs	Bucket	Monthly	The number of general purpose buckets in your account beyond the 2000 bucket account-level free tier
<i>region</i> -Inventory-Objects Listed	Objects	Hourly	The number of objects listed for an object group (objects are grouped by bucket or prefix) with an inventory list
<i>region</i> -Metadata-Updates	Updates	Hourly	Per update fee for updates processed by S3 Metadata
<i>region</i> -Monitoring-Automation-INT	Objects	Hourly	The number of unique objects monitored and auto-tiered in the S3 Intelligent-Tiering storage class
<i>region</i> -MRAP-Out-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).

Usage Type	Units	Granularity	Description	
<i>region</i> -MRAP-In-Bytes	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint out of buckets in a Region (MRAP data routing pricing).	
<i>regiongroup1</i> - <i>regiongroup2</i> -MRAP-Out-Bytes	-	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint from a bucket in <i>regiongroup1</i> to a client in <i>regiongroup2</i> located outside of the AWS network.
<i>regiongroup1</i> - <i>regiongroup2</i> -MRAP-In-Bytes	-	GB	Hourly	The amount of data transferred through an S3 Multi-Region Access Points endpoint to a bucket in <i>regiongroup1</i> from a client in <i>regiongroup2</i> located outside of the AWS network.
<i>region</i> -OverwriteBytes-Copy-GDA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Deep Archive storage	

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Copy-GIR	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Copy-GLACIER	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Copy-INT	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Intelligent-Tiering storage
<i>region</i> -OverwriteBytes-Copy-RRS	GB	Monthly	The amount of data overwritten by a CopyObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Copy-SIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Copy-STANDARD	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Copy-ZIA	GB	Monthly	The amount of data overwritten by a CopyObject operation from S3 One Zone-IA storage
<i>region</i> -OverwriteBytes-Put-GDA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Deep Archive storage
<i>region</i> -OverwriteBytes-Put-GIR	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Instant Retrieval storage.
<i>region</i> -OverwriteBytes-Put-GLACIER	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Glacier Flexible Retrieval storage
<i>region</i> -OverwriteBytes-Put-INT	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -OverwriteBytes-Put-RRS	GB	Monthly	The amount of data overwritten by a PutObject operation from Reduced Redundancy Storage (RRS) storage
<i>region</i> -OverwriteBytes-Put-SIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard-IA storage
<i>region</i> -OverwriteBytes-Put-STANDARD	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 Standard storage
<i>region</i> -OverwriteBytes-Put-ZIA	GB	Monthly	The amount of data overwritten by a PutObject operation from S3 One Zone-IA storage

Usage Type	Units	Granularity	Description
<i>region1-region2</i> -S3RTC-In-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region2</i> to <i>region1</i> by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations
<i>region1-region2</i> -S3RTC-Out-Bytes	GB	Monthly	The amount of data transferred for S3 Replication Time Control (S3 RTC) from <i>region1</i> to <i>region2</i> by the PutObjectReplTime , GetObjectReplTime , InitiateMultipartUploadReplTime , UploadPartReplTime , CompleteMultipartUploadReplTime , and WriteACLReplTime operations

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GDA-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Deep Archive objects ⁶
<i>region</i> -Requests-GDA-Tier2	Count	Hourly	The number of GET and HEAD requests on S3 Glacier Deep Archive objects
<i>region</i> -Requests-GDA-Tier3	Count	Hourly	The number of S3 Glacier Deep Archive standard restore requests
<i>region</i> -Requests-GDA-Tier5	Count	Hourly	The number of Bulk S3 Glacier Deep Archive restore requests
<i>region</i> -Requests-GIR-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Glacier Instant Retrieval objects.
<i>region</i> -Requests-GIR-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval-Tier1 requests on S3 Glacier Instant Retrieval objects.

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-GLACIER-Tier1	Count	Hourly	The number of PUT, COPY, POST, CreateMultipartUpload , UploadPart , or CompleteMultipartUpload requests on S3 Glacier Flexible Retrieval objects ⁶
<i>region</i> -Requests-GLACIER-Tier2	Count	Hourly	The number of GET and all other requests not listed on S3 Glacier Flexible Retrieval objects
<i>region</i> -Requests-INT-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Intelligent-Tiering objects
<i>region</i> -Requests-INT-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests for S3 Intelligent-Tiering objects
<i>region</i> -Requests-SIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 Standard-IA objects
<i>region</i> -Requests-SIA-Tier2	Count	Hourly	The number of GET and all other non-S3 Glacier Instant Retrieval -Tier1 requests on S3 Standard-IA objects

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests for S3 Standard, RRS, and tags, plus LIST requests for all buckets and objects
<i>region</i> -Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests
<i>region</i> -Requests-Tier3	Count	Hourly	The number of lifecycle requests to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive and standard S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier4	Count	Hourly	The number of lifecycle transitions to S3 Glacier Instant Retrieval, S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage
<i>region</i> -Requests-Tier5	Count	Hourly	The number of Bulk S3 Glacier Flexible Retrieval restore requests
<i>region</i> -Requests-Tier6	Count	Hourly	The number of Expedited S3 Glacier Flexible Retrieval restore requests

Usage Type	Units	Granularity	Description
<i>region</i> -Requests-Tier8	Count	Hourly	The number of S3 Access Grants requests
<i>region</i> -Requests-XZ-Tier1	Count	Hourly	The number of PUT or COPY requests on S3 Express One Zone objects
<i>region</i> -Requests-XZ-Tier2	Count	Hourly	The number of GET and all other non-S3 Express One Zone-Tier1 requests on S3 Express One Zone objects
<i>region</i> -Requests-ZIA-Tier1	Count	Hourly	The number of PUT, COPY, or POST requests on S3 One Zone-IA objects
<i>region</i> -Requests-ZIA-Tier2	Count	Hourly	The number of GET and all other non-S3 One Zone-IA-Tier1 requests on S3 One Zone-IA objects
<i>region</i> -Retrieval-GIR	GB	Hourly	The amount of data retrieved from S3 Glacier Instant Retrieval storage.
<i>region</i> -Retrieval-SIA	GB	Hourly	The amount of data retrieved from S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -Retrieval-XZ	GB	Hourly	The portion of the data that exceeds 512 KB in a given retrieval request (PUT or COPY) with S3 Express One Zone storage
<i>region</i> -Retrieval-ZIA	GB	Hourly	The amount of data retrieved from S3 One Zone-IA storage
<i>region</i> -S3DSSE-In-Bytes	GB	Monthly	The amount of data dual-encrypted by Amazon S3
<i>region</i> -S3DSSE-Out-Bytes	GB	Monthly	The amount of dual-encrypted data decrypted by Amazon S3
<i>region</i> -S3G-DataTransfer-In-Bytes	GB	Hourly	The amount of data transferred into Amazon S3 to restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage
<i>region</i> -S3G-DataTransfer-Out-Bytes	GB	Hourly	The amount of data transferred from Amazon S3 to transition objects to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage

Usage Type	Units	Granularity	Description
<i>region</i> -Select-Returned-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard storage
<i>region</i> -Select-Returned-GIR-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Glacier Instant Retrieval storage.
<i>region</i> -Select-Returned-INT-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Returned-SIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 Standard-IA storage
<i>region</i> -Select-Returned-ZIA-Bytes	GB	Hourly	The amount of data returned with Select requests from S3 One Zone-IA storage
<i>region</i> -Select-Scanned-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard storage
<i>region</i> -Select-Scanned-GIR-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
<i>region</i> -Select-Scanned-INT-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Intelligent-Tiering storage
<i>region</i> -Select-Scanned-SIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 Standard-IA storage
<i>region</i> -Select-Scanned-ZIA-Bytes	GB	Hourly	The amount of data scanned with Select requests from S3 One Zone-IA storage
<i>region</i> -Standard-Retrieval-Bytes	GB	Hourly	The amount of data retrieved with standard S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive requests
<i>region</i> -StorageAnalytics-ObjCount	Objects	Hourly	The number of unique objects monitored in each Storage Class Analysis configuration.
<i>region</i> -StorageLens-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens advanced metrics and recommendations.

Usage Type	Units	Granularity	Description
<i>region</i> -StorageLensFreeTier-ObjCount	Objects	Daily	The number of unique objects in each S3 Storage Lens dashboard that are tracked by S3 Storage Lens usage metrics.
StorageObjectCount	Count	Daily	The number of objects stored within a given bucket
<i>region</i> -Tables-CompactedObjects	Objects	Hourly	The number of objects compacted in Amazon S3 table buckets
<i>region</i> -Tables-MonitoredObjects	Objects	Hourly	The number of objects in Amazon S3 table buckets
<i>region</i> -Tables-ProcessedBytes	GB	Hourly	The amount of data processed for compaction in Amazon S3 table buckets
<i>region</i> -Tables-Requests-Tier1	Count	Hourly	The number of PUT requests on Amazon S3 table buckets
<i>region</i> -Tables-Requests-Tier2	Count	Hourly	The number of GET and all other non-Tier1 requests on Amazon S3 table buckets

Usage Type	Units	Granularity	Description
<i>region</i> -Tables-TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Amazon S3 table buckets
<i>region</i> -TagStorage-TagHrs	Tag-Hours	Daily	The total of tags on all objects in the bucket reported by hour
<i>region</i> -TimedStorage-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard storage
<i>region</i> -TimedStorage-GDA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive storage
<i>region</i> -TimedStorage-GDA-Staging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Deep Archive staging storage
<i>region</i> -TimedStorage-GIR-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Instant Retrieval storage.

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-GIR-Sm0bjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Glacier Instant Retrieval storage.
<i>region</i> -TimedStorage-GlacierByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval storage
<i>region</i> -TimedStorage-GlacierStaging	GB-Month	Daily	The number of GB-months that data was stored in S3 Glacier Flexible Retrieval staging storage
<i>region</i> -TimedStorage-INT-FA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Frequent Access tier of S3 Intelligent-Tiering storage ⁵
<i>region</i> -TimedStorage-INT-IA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Infrequent Access tier of S3 Intelligent-Tiering storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-INT-AA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-AIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Archive Instant Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-INT-DAA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in the Deep Archive Access tier of S3 Intelligent-Tiering storage
<i>region</i> -TimedStorage-RRS-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in Reduced Redundancy Storage (RRS) storage
<i>region</i> -TimedStorage-SIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Standard-IA storage

Usage Type	Units	Granularity	Description
<i>region</i> -TimedStorage-SIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 Standard-IA storage ⁴
<i>region</i> -TimedStorage-XZ-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 Express One Zone storage
<i>region</i> -TimedStorage-ZIA-ByteHrs	GB-Month	Daily	The number of GB-months that data was stored in S3 One Zone-IA storage
<i>region</i> -TimedStorage-ZIA-SmObjects	GB-Month	Daily	The number of GB-months that small objects (smaller than 128 KB) were stored in S3 One Zone-IA storage
<i>region</i> -Upload-XZ	GB	Hourly	The amount of data that exceeds 512 KB in a given upload request (PUT or COPY) with S3 Express One Zone

Notes

1. The Global-Bucket-Hrs and Global-Bucket-Hrs-FreeTier usage types apply to general purpose buckets in commercial AWS Regions and AWS GovCloud (US).
2. If you terminate a transfer before completion, the amount of data that is transferred might exceed the amount of data that your application receives. This discrepancy can occur because

a transfer termination request cannot be executed instantaneously, and some amount of data might be in transit, pending execution of the termination request. This data in transit is billed as data transferred "out."

3. When objects that are archived to the S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage class are deleted, overwritten, or transitioned to a different storage class before the minimum storage commitment has passed, which is 90 days for S3 Glacier Instant Retrieval and S3 Glacier Flexible Retrieval, or 180 days for S3 Glacier Deep Archive, there is a prorated charge per gigabyte for the remaining days.
 4. For objects that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
 5. For small objects (smaller than 128 KB) that are in S3 Standard-IA or S3 One Zone-IA storage, when they are deleted, overwritten, or transitioned to a different storage class before 30 days, there is a prorated charge per gigabyte for the remaining days.
 6. There is no minimum billable object size for objects in the S3 Intelligent-Tiering storage class. Objects that are smaller than 128 KB are not monitored or eligible for auto-tiering. Smaller objects are always stored in the S3 Intelligent-Tiering Frequent Access tier.
 7. When you initiate a `CreateMultipartUpload`, `UploadPart`, or `UploadPartCopy` request to either the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, requests are billed at S3 Standard request rates until you complete the multipart upload. After the upload is completed, the single `CompleteMultipartUpload` request is billed at the PUT rate for the destination S3 Glacier storage. In-progress multipart upload parts for a PUT to the S3 Glacier Flexible Retrieval storage class are billed as S3 Glacier Flexible Retrieval Staging Storage at S3 Standard storage rates until the upload is completed. Similarly, in-progress multipart upload parts for a PUT to the S3 Glacier Deep Archive storage class are billed as S3 Glacier Deep Archive Staging Storage at S3 Standard storage rates until the upload is completed.
 8. S3 Express One Zone applies a flat per-request charge for request sizes up to 512 KB. An additional per GB charge is applied for PUT requests and GET requests for the portion of request greater than 512 KB.
 9. For information about supported features for S3 Express One Zone storage class, see [Amazon S3 features not supported by directory buckets](#).
- 10Usage types with units that are billed in GB are calculated in bytes in the usage reports.
- 11A GB-Month is derived by taking the total number of GB-hours, aggregating these over the course of a month, and then dividing by the number of hours in that month. To learn more see, [Frequently Asked Questions: How will I be charged and billed for my use of Amazon S3?](#)

Note

In general, S3 bucket owners are billed for requests with HTTP 200 OK successful responses and HTTP 4XX client error responses. Bucket owners aren't billed for HTTP 5XX server error responses, such as HTTP 503 Slow Down errors. For more information on S3 error codes under HTTP 3XX and 4XX status codes that aren't billed, see [Billing for Amazon S3 error responses](#). For more information about billing charges if your bucket is configured as a Requester Pays bucket, see [How Requester Pays charges work](#).

Tracking Operations in Your Usage Reports

Operations describe the action taken on your AWS object or bucket by the specified usage type. Operations are indicated by self-explanatory codes, such as PutObject or ListBucket. To see which actions on your bucket generated a specific type of usage, use these codes. When you create a usage report, you can choose to include **All Operations**, or a specific operation, for example, GetObject, to report on.

Billing for Amazon S3 error responses

In general, S3 bucket owners are billed for requests with HTTP 200 OK successful responses and HTTP 4XX client error responses. Bucket owners aren't billed for HTTP 5XX server error responses, such as HTTP 503 Slow Down errors. For more information about billing charges if your bucket is configured as a Requester Pays bucket, see [How Requester Pays charges work](#).

The following table lists specific error codes under HTTP 3XX and 4XX status codes that aren't billed. For buckets configured with website hosting, applicable request and other charges will still apply when S3 returns a [custom error document](#) or for custom redirects.

Note

For AccessDenied (HTTP 403 Forbidden), S3 doesn't charge the bucket owner when the request is initiated outside of the bucket owner's individual AWS account or the bucket owner's AWS organization.

HTTP status code	Error code	Description of error code
301 Moved Permanently	PermanentRedirect	The bucket that you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.
	PermanentRedirectControlError	The API operation you are attempting to access must be addressed using the specified endpoint. Send all future requests to this endpoint.
307 Temporary Redirect	TemporaryRedirect	You are being redirected to the bucket while the Domain Name System (DNS) server is being updated.
400 Bad Request	AuthorizationHeaderMalformed	The authorization header that you provided is not valid.

HTTP status code	Error code	Description of error code
	AuthorizationQueryParametersError	The authorization query parameters that you provided are not valid.
	ConnectionClosedByRequester	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.
	DeviceNotActiveError	The device is not currently active.
	EndpointNotFound	Direct requests to the correct endpoint.
	ExpiredToken	The provided token has expired.
	IllegalLocationConstraintException	<p>You are trying to access a bucket from a different Region than where the bucket exists. To avoid this error, use the --region option. For example:</p> <pre>aws s3 cp awsexample.txt s3://amzn-s3-demo-bucket / --region ap-east-1 .</pre>

HTTP status code	Error code	Description of error code
	InvalidArgument	<p>This error might occur for the following reasons:</p> <ul style="list-style-type: none">• The specified argument was not valid.• The request was missing a required header.• The specified argument was incomplete or in the wrong format.• The specified argument must have a length greater than or equal to 3.
	InvalidBucketOwner AWSAccountId	The value of the expected bucket owner parameter must be an AWS account ID.
	InvalidDigest	The Content-MD5 or checksum value that you specified is not valid.

HTTP status code	Error code	Description of error code
400	InvalidEncryptionAlgorithmError	The encryption request that you specified is not valid. The valid value is AES256.
	InvalidHostHeader	The host headers provided in the request used the incorrect style addressing.
	InvalidHttpMethod	The request is made using an unexpected HTTP method.

HTTP status code	Error code	Description of error code
	InvalidRequest	<p>This error might occur for the following reasons:</p> <ul style="list-style-type: none">• The request is using the wrong signature version. Use AWS4-HMAC-SHA256 (Signature Version 4).• An access point can be created only for an existing bucket.• The access point is not in a state where it can be deleted.• An access point can be listed only for an existing bucket.• The next token is not valid.• At least one action must be specified in a lifecycle rule.• At least one lifecycle rule must be specified.•

HTTP status code	Error code	Description of error code
		<p>The number of lifecycle rules must not exceed the allowed limit of 1000 rules.</p> <ul style="list-style-type: none">• The range for the <code>MaxResults</code> parameter is not valid.• SOAP requests must be made over an HTTPS connection.• Amazon S3 Transfer Acceleration is not supported for buckets with non-DNS compliant names.• Amazon S3 Transfer Acceleration is not supported for buckets with periods (.) in their names.• The Amazon S3 Transfer Acceleration endpoint supports only virtual style requests.• Amazon S3 Transfer Acceleration is not

HTTP status code	Error code	Description of error code
		<p>configured on this bucket.</p> <ul style="list-style-type: none">• Amazon S3 Transfer Acceleration is disabled on this bucket.• Amazon S3 Transfer Acceleration is not supported on this bucket. For assistance, contact Support.• Amazon S3 Transfer Acceleration cannot be enabled on this bucket. For assistance, contact Support.• Conflicting values provided in HTTP headers and query parameters.• Conflicting values provided in HTTP headers and POST form fields.• CopyObject request made on objects larger than 5GB in size.

HTTP status code	Error code	Description of error code
	InvalidSessionException	Returned if the session doesn't exist anymore because it timed out or expired.
	InvalidSignature	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see Signing and authenticating REST requests .
	InvalidSOAPRequest	The SOAP request body is not valid.
	InvalidStorageClass	The storage class that you specified is not valid.
	InvalidTag	Your request contains tag input that is not valid. For example, your request might contain duplicate keys, keys or values that are too long, or system tags.
	InvalidToken	The provided token is malformed or otherwise not valid.

HTTP status code	Error code	Description of error code
	InvalidURI	The specified URI couldn't be parsed.
	KeyTooLongError	Your key is too long.
	KMS.DisabledException	The request was rejected because the specified KMS key is not enabled.

HTTP status code	Error code	Description of error code
	KMS.InvalidKeyUsageException	<p>The request was rejected for one of the following reasons:</p> <ul style="list-style-type: none">• The KeyUsage value of the KMS key is incompatible with the API operation.• The encryption algorithm or signing algorithm specified for the operation is incompatible with the type of key material in the KMS key (KeySpec). <p>For encrypting, decrypting, re-encrypting, and generating data keys, the KeyUsage must be ENCRYPT_DECRYPT. For signing and verifying messages, the KeyUsage must be SIGN_VERIFY. For generating and verifying message authentication codes (MACs), the KeyUsage must be GENERATE_VERIFY_MAC. For deriving key agreement secrets, the KeyUsage</p>

HTTP status code	Error code	Description of error code
		<p>must be KEY_AGREE MENT. To find the KeyUsage of a KMS key, use the DescribeKey operation.</p> <p>To find the encryption or signing algorithms supported for a particula r KMS key, use the DescribeKey operation.</p>

HTTP status code	Error code	Description of error code
	KMS.KMSInvalidStateException	<p>The request was rejected because the state of the specified resource is not valid for this request. This exception means one of the following:</p> <ul style="list-style-type: none">• The key state of the KMS key is not compatible with the operation. <p>To find the key state, use the <code>DescribeKey</code> operation. For more information about which key states are compatible with each KMS operation, see Key states of AWS KMS keys in the <i>AWS Key Management Service Developer Guide</i>.</p> <ul style="list-style-type: none">• For cryptographic operations on KMS keys in custom key stores, this exception represents a general failure with many possible causes. To identify the cause, see the error message

HTTP status code	Error code	Description of error code
		that accompanies the exception.
	KMS.NotFoundException LambdaInvalidResponse	The request was rejected because the specified entity or resource could not be found. Returned to the original caller when WriteGetObjectResponse responds with ValidationError to AWS Lambda. See the ValidationError message for more details. Not all cases of ValidationError result in a LambdaInvalidResponse error.

HTTP status code	Error code	Description of error code
	LambdaInvocationFailed	<p>Lambda function invocation failed. Callers might receive the following error when S3 Object Lambda is unable to successfully invoke the configured Lambda function.</p> <p>The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>
	MalformedACLError	<p>The ACL that you provided was not well formed or did not validate against our published schema.</p>
	MalformedPOSTRequest	<p>The body of your POST request is not well-formed multipart/form-data.</p>
	MalformedXML	<p>The XML that you provided was not well formed or did not validate against our published schema.</p>

HTTP status code	Error code	Description of error code
	MaxPostPreDataLengthExceededError	Your POST request fields preceding the upload file were too large.
	MetadataTooLarge	Your metadata headers exceed the maximum allowed metadata size.
	MissingAttachment	A SOAP attachment was expected, but none was found.
	MissingRequestBodyError	You sent an empty XML document as a request.
	MissingSecurityHeader	Your request is missing a required header.
	NoLoggingStatusForKey	There is no such thing as a logging status subresource for a key.
	NotDeviceOwnerError	The device that generated the token is not owned by the authenticated user.
	ResponseInterrupted	Returned to the original caller when an error is encountered while reading the WriteGetObjectResponse body.

HTTP status code	Error code	Description of error code
	RequestHeaderSectionTooLarge	The request header and query parameters used to make the request exceed the maximum allowed sizes
	TokenCodeInvalidError	The serial number and/or token code you provided is not valid.
	UnexpectedContent	This request contains unsupported content.
	UnsupportedArgument	The request contained an unsupported argument.
	UnsupportedSignature	The provided request is signed with an unsupported STS Token version or the signature version is not supported.
	UserKeyMustBeSpecified	The bucket POST request must contain the specified field name. If it is specified, check the order of the fields.
	IncorrectEndpoint	The specified bucket exists in another Region. Direct requests to the correct endpoint.

HTTP status code	Error code	Description of error code
	ValidationError	Validation errors might be returned from the WriteGetObjectResponse API operation and can occur for numerous reasons. See the error message for more details.
403 Forbidden	RequestTimeTooSkewed	The difference between the request time and the server's time is too large.
	SignatureDoesNotMatch	The request signature that the server calculated does not match the signature that you provided. Check your AWS secret access key and signing method. For more information, see REST Authentication and SOAP Authentication .
	NotSignedUp	Your account is not signed up for the Amazon S3 service. You must sign up before you can use Amazon S3. You can sign up at the following URL: https://aws.amazon.com/s3

HTTP status code	Error code	Description of error code
	InvalidSecurity	The provided security credentials are not valid.
	InvalidPayer	All access to this object has been disabled. For further assistance, see Contact Us .
	InvalidAccessKeyId	The AWS access key ID that you provided does not exist in our records.
	AccountProblem	There is a problem with your AWS account that prevents the operation from completing successfully. For further assistance, see Contact Us .
	UnauthorizedAccessError	Applicable in China Regions only. Returned when a request is made to a bucket that doesn't have an ICP license. For more information, see ICP Recordal .
	UnexpectedIPError	Applicable in China Regions only. This request was rejected because the IP was unexpected.

HTTP status code	Error code	Description of error code
	MissingAuthenticationToken	The request was not signed.
	LambdaPermissionError	<p>The caller is not authorized to invoke the Lambda function.</p> <p>The caller must have permission to invoke the Lambda function.</p> <p>Check the policies attached to the caller and ensure that they've been allowed to use <code>lambda:Invoke</code> for the configured function.</p> <p>The error message might contain details about an eventual error returned by the Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>

HTTP status code	Error code	Description of error code
404 Not Found	LambdaNotFound	<p>The AWS Lambda function was not found. The configured Lambda function, version, or alias was not found when attempting to invoke it. Ensure that the S3 Object Lambda Access Point configuration points to the correct Lambda function ARN. The error message might contain details about an eventual error returned by the AWS Lambda service when invoking the function (for example, status code, error code, error message and request ID).</p>
	NoSuchAsyncRequest	The specified request was not found.
	NoSuchObjectLockConfiguration	The specified object does not have an ObjectLock configuration.

HTTP status code	Error code	Description of error code
	NoSuchUpload	The specified multipart upload does not exist. The upload ID might not be valid, or the multipart upload might have been aborted or completed.
	NoSuchWebsiteConfiguration	The specified bucket does not have a website configuration.
	NoTransformationDefined	No transformation found for this Object Lambda Access Point.
	ObjectLockConfigurationNotFoundError	The Object Lock configuration does not exist for this bucket.
	MethodNotAllowed	The specified method is not allowed against this resource.
409 Conflict	BucketAlreadyExists	The requested bucket name is not available. The bucket namespace is shared by all users of the system. Specify a different name and try again.

HTTP status code	Error code	Description of error code	
	InvalidBucketState	The request is not valid for the current state of the bucket.	
	OperationAborted	A conflicting conditional operation is currently in progress against this resource. Try again.	
411 Length Required	MissingContentLength	You must provide the Content-Length HTTP header.	
412 Precondition Failed	RequestIsNotMultiPartContent	A bucket POST request must be of the enclosure-type multipart/form-data.	
416 Requested Range Not Satisfiable	InvalidRange	The requested range is not valid for the request. Try another range.	

Understanding and managing Amazon S3 storage classes

Each object in Amazon S3 has a storage class associated with it. By default, objects in S3 are stored in the S3 Standard storage class, however Amazon S3 offers a range of other storage classes for the objects that you store. You choose a class depending on your use case scenario and performance access requirements. Choosing a storage class designed for your use case lets you optimize storage costs, performance, and availability for your objects. All of these storage classes offer high durability.

The following sections provide details of the various storage classes and how to set the storage class for your objects.

Topics

- [Storage classes for frequently accessed objects](#)
- [Storage class for automatically optimizing data with changing or unknown access patterns](#)
- [Storage classes for infrequently accessed objects](#)
- [Storage classes for rarely accessed objects](#)
- [Storage class for Amazon S3 on Outposts](#)

- [Amazon S3 analytics – Storage Class Analysis](#)
- [Managing storage costs with Amazon S3 Intelligent-Tiering](#)
- [Understanding S3 Glacier storage classes for long-term data storage](#)
- [Working with archived objects](#)

Storage classes for frequently accessed objects

For performance-sensitive use cases (those that require millisecond access time) and frequently accessed data, Amazon S3 provides the following storage classes:

- **S3 Standard (STANDARD)** – The default storage class. If you don't specify the storage class when you upload an object, Amazon S3 assigns the S3 Standard storage class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use [Amazon S3 analytics – Storage Class Analysis](#).
- **S3 Express One Zone (EXPRESS_ONEZONE)** – Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. S3 Express One Zone is the lowest latency cloud object storage class available today, with data access speed up to 10x faster and with request costs 50 percent lower than S3 Standard. With S3 Express One Zone, your data is redundantly stored on multiple devices within a single Availability Zone. For more information, see [S3 Express One Zone](#).

- **Reduced Redundancy Storage (REDUCED_REDUNDANCY)** – The Reduced Redundancy Storage (RRS) class is designed for noncritical, reproducible data that can be stored with less redundancy than the S3 Standard storage class.

 **Important**

We recommend not using this storage class. The S3 Standard storage class is more cost-effective.

For durability, RRS objects have an average annual expected loss of 0.01 percent of objects. If an RRS object is lost, when requests are made to that object, Amazon S3 returns a 405 error.

Storage class for automatically optimizing data with changing or unknown access patterns

S3 Intelligent-Tiering (INTELLIGENT_TIERING) is an Amazon S3 storage class that's designed to optimize storage costs by automatically moving data to the most cost-effective access tier, without performance impact or operational overhead. S3 Intelligent-Tiering is the only cloud storage class that delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. S3 Intelligent-Tiering is the ideal storage class when you want to optimize storage costs for data that has unknown or changing access patterns. There are no retrieval fees for S3 Intelligent-Tiering.

For a small monthly object monitoring and automation fee, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers. S3 Intelligent-Tiering delivers automatic storage cost savings in three low-latency and high-throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is designed for 99.9% availability and 99.999999999% durability.

S3 Intelligent-Tiering automatically stores objects in three access tiers:

- **Frequent Access** – Objects that are uploaded or transitioned to S3 Intelligent-Tiering are automatically stored in the Frequent Access tier.
- **Infrequent Access** – S3 Intelligent-Tiering moves objects that have not been accessed in 30 consecutive days to the Infrequent Access tier.

- **Archive Instant Access** – With S3 Intelligent-Tiering, any existing objects that have not been accessed for 90 consecutive days are automatically moved to the Archive Instant Access tier.

In addition to these three tiers, S3 Intelligent-Tiering offers two optional archive access tiers:

- **Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days.
- **Deep Archive Access** – S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier automatically archives objects that have not been accessed for a minimum of 180 consecutive days.

 **Note**

- Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower-cost storage with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.
- Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, first restore the object by using `RestoreObject`.

You can [move newly created data to S3 Intelligent-Tiering](#), setting it as your default storage class. You can also choose to activate one or both of the archive access tiers by using the [PutBucketIntelligentTieringConfiguration](#) API operation, the AWS CLI, or the Amazon S3 console. For more information about using S3 Intelligent-Tiering and activating the archive access tiers, see [Using S3 Intelligent-Tiering](#).

To access objects in the Archive Access or Deep Archive Access tiers, you first need to restore them. For more information, see [Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers](#).

Note

If the size of an object is less than 128 KB, it is not monitored and not eligible for auto-tiering. Smaller objects are always stored in the Frequent Access tier. For more information about S3 Intelligent-Tiering, see [S3 Intelligent-Tiering access tiers](#).

Storage classes for infrequently accessed objects

The **S3 Standard-IA** and **S3 One Zone-IA** storage classes are designed for long-lived and infrequently accessed data. (IA stands for *infrequent access*.) S3 Standard-IA and S3 One Zone-IA objects are available for millisecond access (similar to the S3 Standard storage class). Amazon S3 charges a retrieval fee for these objects, so they are most suitable for infrequently accessed data. For pricing information, see [Amazon S3 pricing](#).

For example, you might choose the S3 Standard-IA and S3 One Zone-IA storage classes to do the following:

- For storing backups.
- For older data that is accessed infrequently, but that still requires millisecond access. For example, when you upload data, you might choose the S3 Standard storage class, and use lifecycle configuration to tell Amazon S3 to transition the objects to the S3 Standard-IA or S3 One Zone-IA class.

For more information about lifecycle management, see [Managing the lifecycle of objects](#).

Note

The S3 Standard-IA and S3 One Zone-IA storage classes are suitable for objects larger than 128 KB that you plan to store for at least 30 days. If an object is less than 128 KB, Amazon S3 charges you for 128 KB. If you delete an object before the end of the 30-day minimum storage duration period, you are charged for 30 days. Objects that are deleted, overwritten, or transitioned to a different storage class before 30 days will incur the normal storage usage charge plus a pro-rated charge for the remainder of the 30-day minimum. For pricing information, see [Amazon S3 pricing](#).

These storage classes differ as follows:

- **S3 Standard-IA (STANDARD_IA)** – Amazon S3 stores the object data redundantly across multiple geographically separated Availability Zones (similar to the S3 Standard storage class). S3 Standard-IA objects are resilient to the loss of an Availability Zone. This storage class offers greater availability and resiliency than the S3 One Zone-IA class. To help you optimize costs between S3 Standard and S3 Standard-IA you can use [Amazon S3 analytics – Storage Class Analysis](#)
- **S3 One Zone-IA (ONEZONE_IA)** – Amazon S3 stores the object data in only one Availability Zone, which makes it less expensive than S3 Standard-IA. However, the data is not resilient to the physical loss of the Availability Zone resulting from disasters, such as earthquakes and floods. The S3 One Zone-IA storage class is as durable as S3 Standard-IA, but it is less available and less resilient. For a comparison of storage class durability and availability, see [Comparing the Amazon S3 storage classes](#) at the end of this section. For pricing information, see [Amazon S3 pricing](#). For data residency and isolation use cases, you can create directory buckets in AWS Local Zones and use the S3 Express One Zone (EXPRESS_ONEZONE) and S3 One Zone-IA (ONEZONE_IA) storage classes. For more information about directory buckets in Local Zones, see [Data residency workloads](#).

We recommend the following:

- **S3 Standard-IA (STANDARD_IA)** – Use for your primary or only copy of data that can't be re-created.
- **S3 One Zone-IA (ONEZONE_IA)** – Use if you can re-create the data if the Availability Zone fails, for object replicas when configuring S3 Cross-Region Replication (CRR). Also, for data residency and isolation, you can create directory buckets in AWS Local Zones and use the S3 One Zone-IA storage class.

Storage classes for rarely accessed objects

The **S3 Glacier Instant Retrieval (GLACIER_IR)**, **S3 Glacier Flexible Retrieval (GLACIER)**, and **S3 Glacier Deep Archive (DEEP_ARCHIVE)** storage classes are designed for low-cost, long-term data storage and data archiving. These storage classes require minimum storage durations and retrieval fees making them most effective for rarely accessed data. For more information about S3 Glacier storage classes, see [Understanding S3 Glacier storage classes for long-term data storage](#).

Amazon S3 provides the following S3 Glacier storage classes:

- **S3 Glacier Instant Retrieval (GLACIER_IR)** – Use for long-term data that's rarely accessed and requires milliseconds retrieval. Data in this storage class is available for real-time access.
- **S3 Glacier Flexible Retrieval (GLACIER)** – Use for archives where portions of the data might need to be retrieved in minutes. Data in this storage class is archived, and not available for real-time access.
- **S3 Glacier Deep Archive (DEEP_ARCHIVE)** – Use for archiving data that rarely needs to be accessed. Data in this storage class is archived, and not available for real-time access.

Retrieving archived objects

You can set the storage class of an object to S3 Glacier Flexible Retrieval (GLACIER) or S3 Glacier Deep Archive (DEEP_ARCHIVE) in the same ways that you do for the other storage classes as described in the section [Setting the storage class of an object](#). However, S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive objects are archived, and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#).

 **Note**

When you use S3 Glacier storage classes, your objects remain in Amazon S3. You can't access them directly through the separate Amazon S3 Glacier service. For information about the Amazon S3 Glacier service, see the [Amazon S3 Glacier Developer Guide](#).

Storage class for Amazon S3 on Outposts

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use the same API operations and features on AWS Outposts as you do on Amazon S3, including access policies, encryption, and tagging. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API.

S3 on Outposts provides a new storage class, S3 Outposts (OUTPOSTS). The S3 Outposts storage class is available only for objects stored in buckets on Outposts. If you try to use this storage class with an S3 bucket in an AWS Region, an InvalidStorageClass error occurs. In addition, if you try to use other S3 storage classes with objects stored in S3 on Outposts buckets, the same error occurs.

Objects stored in the S3 Outposts (OUTPOSTS) storage class are always encrypted by using server-side encryption with Amazon S3 managed encryption keys (SSE-S3). For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#).

You can also explicitly choose to encrypt objects stored in the S3 Outposts storage class by using server-side encryption with customer-provided encryption keys (SSE-C). For more information, see [Using server-side encryption with customer-provided keys \(SSE-C\)](#).

 **Note**

S3 on Outposts doesn't support server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS).

For more information about S3 on Outposts, see [What is S3 on Outposts](#) in the *Amazon S3 on Outposts User Guide*.

Comparing the Amazon S3 storage classes

The following table compares the storage classes, including their availability, durability, minimum storage duration, and other considerations.

Storage Class	Designed for	Durability (designed for)	Availability (designed for)	Availability Zones	Min storage duration	Min billable object size	Other Considerations
STANDARD	Frequently accessed data	99.99999999%	99.99%	≥ 3	None	None	None
STANDARD_IA	Long-lived, infrequently accessed data	99.99999999%	99.9%	≥ 3	30 days	128 KB	Per GB retrieval fees apply.
INTELLIGENT_TIERING	Long-lived data with changing or unknown access patterns	99.99999999%	99.9%	≥ 3	30 days	None	Monitoring and automation fees per object apply. No retrieval fees.
ONEZONE_IA	Long-lived, infrequently accessed, non-critical data	99.99999999%	99.5%	1	30 days	128 KB	Per GB retrieval fees apply. Not resilient to the loss of the Availability Zone.
GLACIER	Long-term data archiving with retrieval times ranging from minutes to hours	99.99999999%	99.99% (after you restore objects)	≥ 3	90 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
DEEP_ARCHIVE	Archiving rarely accessed data with a default retrieval time of 12 hours	99.99999999%	99.99% (after you restore objects)	≥ 3	180 days	None	Per GB retrieval fees apply. You must first restore archived objects before you can access them. For more information, see Restoring Archived Objects .
RRS (Not recommended)	Frequently accessed, non-critical data	99.99%	99.99%	≥ 3	None	None	None

* S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Flexible Retrieval rate (required to identify

and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to S3 Glacier Flexible Retrieval. For more information about storage classes, see [Amazon S3 storage classes](#).

** S3 Glacier Deep Archive requires 40 KB of additional metadata for each archived object. This includes 32 KB of metadata charged at the S3 Glacier Deep Archive rate (required to identify and retrieve your data), and an additional 8 KB data charged at the S3 Standard rate. The S3 Standard rate is required to maintain the user-defined name and metadata for objects archived to Amazon S3 Glacier Deep Archive. For more information about storage classes, see [Amazon S3 storage classes](#).

Be aware that all of the storage classes except for S3 One Zone-IA (ONEZONE_IA) and S3 Express One Zone (EXPRESS_ONEZONE) are designed to be resilient to the physical loss of an Availability Zone resulting from disasters. Also, consider costs, in addition to the performance requirements of your application scenario. For storage class pricing, see [Amazon S3 pricing](#).

Setting the storage class of an object

You can specify a storage class for an object when you upload it. If you don't, Amazon S3 uses the default Amazon S3 Standard storage class for objects in general purpose buckets. You can also change the storage class of an object that's already stored in an Amazon S3 general purpose bucket to any other storage class using the Amazon S3 console, AWS SDKs, or the AWS Command Line Interface (AWS CLI). All of these approaches use Amazon S3 API operations to send requests to Amazon S3.

 **Note**

You can't change the storage class of objects stored in directory buckets.

You can direct Amazon S3 to change the storage class of objects automatically by adding an S3 Lifecycle configuration to a bucket. For more information, see [Managing the lifecycle of objects](#).

When setting up a S3 Replication configuration, you can set the storage class for replicated objects to any other storage class. However, you can't replicate objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For more information, see [Replication configuration file elements](#).

When setting the storage class programmatically you provide the value of the storage class. The following is a list of console names for storage classes with their corresponding API values:

- **Reduced Redundancy Storage** – REDUCED_REDUNDANCY
- **S3 Express One Zone** – EXPRESS_ONEZONE
- **S3 Glacier Deep Archive** – DEEP_ARCHIVE
- **S3 Glacier Flexible Retrieval** – GLACIER
- **S3 Glacier Instant Retrieval** – GLACIER_IR
- **S3 Intelligent-Tiering** – INTELLIGENT_TIERING
- **S3 One Zone-IA** – ONEZONE_IA
- **S3 Standard** – STANDARD
- **S3 Standard-IA** – STANDARD_IA

Setting the storage class on a new object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

To set the storage class when uploading a new object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at: <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to upload your folders or files to.
4. Choose **Upload**.
5. In the **Upload** window, choose **Properties**.
6. Under Storage class, choose a storage classes for the files you're uploading.
7. (Optional) Configure any additional properties for the files you're uploading, For more information, see [Uploading objects](#)
8. In the Upload window, do one of the following:
 - Drag files and folders to the Upload window.

- Choose **Add file or Add folder**, choose the files or folders to upload, and choose **Open**.
9. At the bottom of the page, Choose **Upload**.

Using the REST API

You can specify the storage class on an object when you create it using the PutObject, POST Object Object, and CreateMultipartUpload API operations, add the x-amz-storage-class request header. If you don't add this header, Amazon S3 uses the default S3 Standard (STANDARD) storage class.

This example request uses the [PutObject](#) command to set the storage class on a new object to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: DEEP_ARCHIVE
```

Using the AWS CLI

This example uses the put-object command to upload the *my_images.tar.bz2* to *amzn-s3-demo-bucket1* in the *GLACIER* storage class:

```
aws s3api put-object --bucket amzn-s3-demo-bucket1 --key dir-1/my_images.tar.bz2 --
storage-class GLACIER --body my_images.tar.bz2
```

If the object size is more than 5 GB, use the following command to set the storage class:

```
aws s3 cp large_test_file s3://amzn-s3-demo-bucket1 --storage-class GLACIER
```

Changing the storage class for an existing object

To set the storage class when you upload an object, you can use the following methods.

Using the S3 console

You can change an object's storage class using the Amazon S3 console if the object size is less than 5 GB. If larger, we recommend adding an S3 Lifecycle configuration to change the object's storage class.

To change the storage class of an object in the console:

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket containing the objects you want to change.
4. Select the check box to the left of the names of the objects you want to change.
5. On the **Actions** menu, choose **Edit storage class** from the list of options that appears.
6. Select from the storage classes available for your object.
7. Under **Additional copy settings**, choose whether you want to **Copy source settings**, **Don't specify settings**, or **Specify settings**. **Copy source settings** is the default option. If you only want to copy the object without the source settings attributes, choose **Don't specify settings**. Choose **Specify settings** to specify settings for storage class, ACLs, object tags, metadata, server-side encryption, and additional checksums.
8. Choose **Save changes** in the bottom-right corner. Amazon S3 saves your changes.

Using the REST API

To change the storage class of an existing object, use the following methods.

This example request uses the [PutObject](#) command to set the storage class on a new object to S3 Intelligent-Tiering:

```
PUT /my-image.jpg HTTP/1.1
Host: amzn-s3-demo-bucket1.s3.Region.amazonaws.com
Date: Wed, 12 Oct 2009 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
```

```
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: DEEP_ARCHIVE
```

Using the AWS CLI

This example uses the cp command to change the storage class of the of an existing object from it's current storage class to *DEEP_ARCHIVE* storage class:

```
aws s3 cp object_S3_URI object_S3_URI --storage-class DEEP_ARCHIVE
```

Restricting access policy permissions to a specific storage class

When you grant access policy permissions for Amazon S3 operations, you can use the s3:x-amz-storage-class condition key to restrict which storage class to use when storing uploaded objects. For example, when you grant the s3:PutObject permission, you can restrict object uploads to a specific storage class. For an example policy, see [Example: Restricting object uploads to objects with a specific storage class](#).

For more information about using conditions in policies and a complete list of Amazon S3 condition keys, see the following topics:

- [Actions, resources, and condition keys for Amazon S3](#) in the *Service Authorization Reference*
For more information about the permissions to S3 API operations by S3 resource types, see [Required permissions for Amazon S3 API operations](#).
- [Bucket policy examples using condition keys](#)

Amazon S3 analytics – Storage Class Analysis

By using Amazon S3 analytics *Storage Class Analysis* you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. This new Amazon S3 analytics feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. You can configure storage class analysis to analyze all the objects in a bucket. Or, you can configure filters to group objects together for analysis by common prefix (that is, objects that have names that begin with a common string), by object tags, or by both prefix and tags. You'll most likely find that filtering by object groups is the best way to benefit from storage class analysis.

Important

Storage class analysis only provides recommendations for Standard to Standard IA classes.

You can have multiple storage class analysis filters per bucket, up to 1,000, and will receive a separate analysis for each filter. Multiple filter configurations allow you analyze specific groups of objects to improve your lifecycle configurations that transition objects to STANDARD_IA.

Storage class analysis provides storage usage visualizations in the Amazon S3 console that are updated daily. You can also export this daily usage data to an S3 bucket and view them in a spreadsheet application, or with business intelligence tools, like Amazon QuickSight.

There are costs associated with the storage class analysis. For pricing information, see *Management and replication* [Amazon S3 pricing](#).

Topics

- [How do I set up storage class analysis?](#)
- [How do I use storage class analysis?](#)
- [How can I export storage class analysis data?](#)
- [Configuring storage class analysis](#)

How do I set up storage class analysis?

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

- For information about how to configure storage class analysis in the Amazon S3 console, see [Configuring storage class analysis](#).
- To use the Amazon S3 API, use the [PutBucketAnalyticsConfiguration](#) REST API, or the equivalent, from the AWS CLI or AWS SDKs.

How do I use storage class analysis?

You use storage class analysis to observe your data access patterns over time to gather information to help you improve the lifecycle management of your STANDARD_IA storage. After you configure a filter, you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. However, storage class analysis observes the access patterns of a filtered data set for 30 days or longer to gather information for analysis before giving a result. The analysis continues to run after the initial result and updates the result as the access patterns change.

When you first configure a filter, the Amazon S3 console may take a moment to analyze your data.

Storage class analysis observes the access patterns of a filtered object data set for 30 days or longer to gather enough information for the analysis. After storage class analysis has gathered sufficient information, you'll see a message in the Amazon S3 console that analysis is complete.

When performing the analysis for infrequently accessed objects storage class analysis looks at the filtered set of objects grouped together based on age since they were uploaded to Amazon

S3. Storage class analysis determines if the age group is infrequently accessed by looking at the following factors for the filtered data set:

- Objects in the STANDARD storage class that are larger than 128 KB.
- How much average total storage you have per age group.
- Average number of bytes transferred out (not frequency) per age group.
- Analytics export data only includes requests with data relevant to storage class analysis. This might cause differences in the number of requests, and the total upload and request bytes compared to what are shown in storage metrics or tracked by your own internal systems.
- Failed GET and PUT requests are not counted for the analysis. However, you will see failed requests in storage metrics.

How Much of My Storage did I Retrieve?

The Amazon S3 console graphs how much of the storage in the filtered data set has been retrieved for the observation period.

What Percentage of My Storage did I Retrieve?

The Amazon S3 console also graphs what percentage of the storage in the filtered data set has been retrieved for the observation period.

As stated earlier in this topic, when you are performing the analysis for infrequently accessed objects, storage class analysis looks at the filtered set of objects grouped together based on the age since they were uploaded to Amazon S3. The storage class analysis uses the following predefined object age groups:

- Amazon S3 Objects less than 15 days old
- Amazon S3 Objects 15-29 days old
- Amazon S3 Objects 30-44 days old
- Amazon S3 Objects 45-59 days old
- Amazon S3 Objects 60-74 days old
- Amazon S3 Objects 75-89 days old
- Amazon S3 Objects 90-119 days old
- Amazon S3 Objects 120-149 days old

- Amazon S3 Objects 150-179 days old
- Amazon S3 Objects 180-364 days old
- Amazon S3 Objects 365-729 days old
- Amazon S3 Objects 730 days and older

Usually it takes about 30 days of observing access patterns to gather enough information for an analysis result. It might take longer than 30 days, depending on the unique access pattern of your data. However, after you configure a filter you'll start seeing data analysis based on the filter in the Amazon S3 console in 24 to 48 hours. You can see analysis on a daily basis of object access broken down by object age group in the Amazon S3 console.

How Much of My Storage is Infrequently Accessed?

The Amazon S3 console shows the access patterns grouped by the predefined object age groups. The **Frequently accessed** or **Infrequently accessed** text shown is meant as a visual aid to help you in the lifecycle creation process.

How can I export storage class analysis data?

You can choose to have storage class analysis export analysis reports to a comma-separated values (CSV) flat file. Reports are updated daily and are based on the object age group filters you configure. When using the Amazon S3 console you can choose the export report option when you create a filter. When selecting data export you specify a destination bucket and optional destination prefix where the file is written. You can export the data to a destination bucket in a different account. The destination bucket must be in the same region as the bucket that you configure to be analyzed.

You must create a bucket policy on the destination bucket to grant permissions to Amazon S3 to verify what AWS account owns the bucket and to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

After you configure storage class analysis reports, you start getting the exported report daily after 24 hours. After that, Amazon S3 continues monitoring and providing daily exports.

You can open the CSV file in a spreadsheet application or import the file into other applications like [Amazon QuickSight](#). For information on using Amazon S3 files with Amazon QuickSight, see [Create a Data Set Using Amazon S3 Files](#) in the *Amazon QuickSight User Guide*.

Data in the exported file is sorted by date within object age group as shown in following examples. If the storage class is STANDARD the row also contains data for the columns ObjectAgeForSIATransition and RecommendedObjectAgeForSIATransition.

Date	ConfigId	Filter	StorageClass	ObjectAge	ObjectCount	DataUploaded_MB	Storage_MB	DataRetrieved_MB	GetRequestCount	CumulativeAccessRatio	ObjectAgeForSIATransition	RecommendedObjectAgeForSIATransition
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/2/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	000-014			0.4313			0		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	000-014		0.4313				0		
9/5/2021	SalesMaterial	SalesMaterial	STANDARD	000-014						0.04096734		

At the end of the report the object age group is given as ALL. The ALL rows contain cumulative totals, including objects smaller than 128 KB, for all the age groups for that day.

8/24/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/3/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02426125 015-029		
8/28/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03545875 015-029		
8/17/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/25/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
9/6/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.0209529 015-029		
9/4/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.02304819 015-029		
8/22/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/21/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		
8/30/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0.03073092 015-029		
8/20/2021	SalesMaterial	SalesMaterial	STANDARD	ALL	3	0.4599				0 000-014		

The next section describes the columns used in the report.

Exported file layout

The following table describes the Amazon S3 storage class analysis export file layout.

Configuring storage class analysis

By using the Amazon S3 analytics storage class analysis tool, you can analyze storage access patterns to help you decide when to transition the right data to the right storage class. Storage class analysis observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. For more information about STANDARD_IA, see the [Amazon S3 FAQ](#) and [Understanding and managing Amazon S3 storage classes](#).

You set up storage class analysis by configuring what object data you want to analyze. You can configure storage class analysis to do the following:

- **Analyze the entire contents of a bucket.**

You'll receive an analysis for all the objects in the bucket.

- **Analyze objects grouped together by prefix and tags.**

You can configure filters that group objects together for analysis by prefix, or by object tags, or by a combination of prefix and tags. You receive a separate analysis for each filter you configure. You can have multiple filter configurations per bucket, up to 1,000.

- **Export analysis data.**

When you configure storage class analysis for a bucket or filter, you can choose to have the analysis data exported to a file each day. The analysis for the day is added to the file to form a historic analysis log for the configured filter. The file is updated daily at the destination of your choice. When selecting data to export, you specify a destination bucket and optional destination prefix where the file is written.

You can use the Amazon S3 console, the REST API, or the AWS CLI or AWS SDKs to configure storage class analysis.

⚠ Important

Storage class analysis does not give recommendations for transitions to the ONEZONE_IA or S3 Glacier Flexible Retrieval storage classes.

If you want to configure storage class analysis to export your findings as a .csv file and the destination bucket uses default bucket encryption with a AWS KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

For more information about analytics, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the S3 console

To configure storage class analysis

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets** or **Directory buckets**.
3. In the buckets list, choose the name of the bucket for which you want to configure storage class analysis.
4. Choose the **Metrics** tab.

5. Under **Storage Class Analysis**, choose **Create analytics configuration**.
6. Type a name for the filter. If you want to analyze the whole bucket, leave the **Prefix** field empty.
7. In the **Prefix** field, type text for the prefix for the objects that you want to analyze.
8. To add a tag, choose **Add tag**. Enter a key and value for the tag. You can enter one prefix and multiple tags.
9. Optionally, you can choose **Enable** under **Export CSV** to export analysis reports to a comma-separated values (.csv) flat file. Choose a destination bucket where the file can be stored. You can type a prefix for the destination bucket. The destination bucket must be in the same AWS Region as the bucket for which you are setting up the analysis. The destination bucket can be in a different AWS account.

If the destination bucket for the .csv file uses default bucket encryption with a KMS key, you must update the AWS KMS key policy to grant Amazon S3 permission to encrypt the .csv file. For instructions, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

10. Choose **Create Configuration**.

Amazon S3 creates a bucket policy on the destination bucket that grants Amazon S3 write permission. This will allow it to write the export data to the bucket.

If an error occurs when you try to create the bucket policy, you'll be given instructions on how to fix it. For example, if you chose a destination bucket in another AWS account and do not have permissions to read and write to the bucket policy, you'll see the following message. You must have the destination bucket owner add the displayed bucket policy to the destination bucket. If the policy is not added to the destination bucket you won't get the export data because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, then the correct account ID of the source bucket must be substituted in the policy.

For information about the exported data and how the filter works, see [Amazon S3 analytics – Storage Class Analysis](#).

Using the REST API

To configure Storage Class Analysis using the REST API, use the [PutBucketAnalyticsConfiguration](#). You can also use the equivalent operation with the AWS CLI or AWS SDKs.

You can use the following REST APIs to work with Storage Class Analysis:

- [DELETE Bucket Analytics configuration](#)
- [GET Bucket Analytics configuration](#)
- [List Bucket Analytics Configuration](#)

Managing storage costs with Amazon S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class is designed to optimize storage costs by automatically moving data to the most cost-effective access tier when access patterns change, without operational overhead or impact on performance. For a small monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects that have not been accessed to lower-cost access tiers.

S3 Intelligent-Tiering delivers automatic storage cost savings in three low latency and high throughput access tiers. For data that can be accessed asynchronously, you can choose to activate automatic archiving capabilities within the S3 Intelligent-Tiering storage class. There are no retrieval charges in S3 Intelligent-Tiering. If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier. No additional tiering charges apply when objects are moved between access tiers within the S3 Intelligent-Tiering storage class.

S3 Intelligent-Tiering is the recommended storage class for data with unknown, changing, or unpredictable access patterns, independent of object size or retention period, such as data lakes, data analytics, and new applications.

The S3 Intelligent-Tiering storage class supports all Amazon S3 features, including the following:

- S3 Inventory, for verifying the access tier of objects
- S3 Replication, for replicating data to any AWS Region
- S3 Storage Lens, for viewing storage usage and activity metrics
- Server-side encryption, for protecting object data
- S3 Object Lock, for preventing accidental deletion of data
- AWS PrivateLink, for accessing Amazon S3 through a private endpoint in a virtual private cloud (VPC)

For information about using S3 Intelligent-Tiering, see the following sections:

Topics

- [How S3 Intelligent-Tiering works](#)
- [Using S3 Intelligent-Tiering](#)
- [Managing S3 Intelligent-Tiering](#)

How S3 Intelligent-Tiering works

The Amazon S3 Intelligent-Tiering storage class automatically stores objects in three access tiers. One tier is optimized for frequent access, one lower-cost tier is optimized for infrequent access, and another very low-cost tier is optimized for rarely accessed data. For a low monthly object monitoring and automation charge, S3 Intelligent-Tiering monitors access patterns and automatically moves objects to the Infrequent Access tier when they haven't been accessed for 30 consecutive days. After 90 days of no access, the objects are moved to the Archive Instant Access tier without performance impact or operational overhead.

To get the lowest storage cost for data that can be accessed in minutes to hours, activate archiving capabilities to add two additional access tiers. You can tier down objects to the Archive Access tier, the Deep Archive Access tier, or both. With Archive Access, S3 Intelligent-Tiering moves objects that have not been accessed for a minimum of 90 consecutive days to the Archive Access tier. With Deep Archive Access, S3 Intelligent-Tiering moves objects to the Deep Archive Access tier after a minimum of 180 consecutive days of no access. For both tiers, you can configure the number of days of no access based on your needs.

The following actions constitute access that prevents tiering your objects down to the Archive Access tier or the Deep Archive Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with S3 Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), [CompleteMultipartUpload](#), [ListParts](#), or [SelectObjectContent](#).

For example, if your objects are accessed through `SelectObjectContent` before your specified number of days of no access (for example, 180 days), that action resets the timer. Your objects won't move to the Archive Access tier or the Deep Archive Access tier until the time after the last `SelectObjectContent` request reaches your specified number of days.

If an object in the Infrequent Access tier or Archive Instant Access tier is accessed later, it is automatically moved back to the Frequent Access tier.

The following actions constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier:

- Downloading or copying an object through the Amazon S3 console.
- Invoking [CopyObject](#), [UploadPartCopy](#), or replicating objects with Batch Replication. In these cases, the source objects of the copy or replication operations are tiered up.
- Invoking [GetObject](#), [PutObject](#), [RestoreObject](#), [CompleteMultipartUpload](#), or [ListParts](#).

Other actions **don't** constitute access that automatically moves objects from the Infrequent Access tier or the Archive Instant Access tier back to the Frequent Access tier. The following is a sample, not a definitive list, of such actions:

- Invoking [HeadObject](#), [GetObjectTagging](#), [PutObjectTagging](#), [ListObjects](#), [ListObjectsV2](#), or [ListObjectVersions](#).
- Invoking [SelectObjectContent](#) doesn't constitute access that tiers objects up to a Frequent Access tier. In addition, it doesn't prevent tiering objects down from the Frequent Access tier to the Infrequent Access tier, and then to the Archive Instant Access tier.

You can use S3 Intelligent-Tiering as your default storage class for newly created data by specifying INTELLIGENT-TIERING in the [x-amz-storage-class request header](#) when calling the PutObject, CopyObject, or CreateMultipartUpload operations. S3 Intelligent-Tiering is designed for 99.9% availability and 99.99999999% durability.

 **Note**

If the size of an object is less than 128 KB, it is not monitored and is not eligible for automatic tiering. Smaller objects are always stored in the Frequent Access tier.

S3 Intelligent-Tiering access tiers

The following section explains the different automatic and optional access tiers. When objects move between access tiers, the storage class remains the same (S3 Intelligent-Tiering).

Frequent Access tier (automatic)

This is the default access tier that any object created or transitioned to S3 Intelligent-Tiering begins its lifecycle in. An object remains in this tier as long as it is being accessed. The Frequent Access tier provides low latency and high-throughput performance.

Infrequent Access tier (automatic)

If an object is not accessed for 30 consecutive days, the object moves to the Infrequent Access tier. The Infrequent Access tier provides low latency and high-throughput performance.

Archive Instant Access tier (automatic)

If an object is not accessed for 90 consecutive days, the object moves to the Archive Instant Access tier. The Archive Instant Access tier provides low latency and high-throughput performance.

Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Archive Access tier for data that can be accessed asynchronously. After activation, the Archive Access tier automatically archives objects that have not been accessed for a minimum of 90 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Archive Access tier has the same performance as the [S3 Glacier Flexible Retrieval](#) storage class.

Standard retrieval times for this access tier can range from 3–5 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within minutes. For more information about retrieval options and times, see [the section called “Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Only activate the Archive Access tier for 90 days if you want to bypass the Archive Instant Access tier. The Archive Access tier delivers slightly lower storage costs, with minute-to-hour retrieval times. The Archive Instant Access tier delivers millisecond access and high-throughput performance.

Deep Archive Access tier (optional)

S3 Intelligent-Tiering provides you with the option to activate the Deep Archive Access tier for data that can be accessed asynchronously. After activation, the Deep Archive Access tier

automatically archives objects that have not been accessed for a minimum of 180 consecutive days. You can extend the last access time for archiving to a maximum of 730 days. The Deep Archive Access tier has the same performance as the [S3 Glacier Deep Archive](#) storage class.

Standard retrieval of objects in this access tier occurs within 12 hours. If you initiate your restore request by using S3 Batch Operations, your restore starts within 9 hours. For more information about retrieval options and times, see [the section called “Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers”](#).

Note

Activate the Archive Access and Deep Archive Access tiers only if your objects can be accessed asynchronously by your application. If the object that you are retrieving is stored in the Archive Access or Deep Archive Access tiers, you must first restore the object by using the `RestoreObject` operation.

Using S3 Intelligent-Tiering

You can use the S3 Intelligent-Tiering storage class to automatically optimize storage costs. S3 Intelligent-Tiering delivers automatic cost savings by moving data on a granular object level between access tiers when access patterns change. For data that can be accessed asynchronously, you can choose to enable automatic archiving within the S3 Intelligent-Tiering storage class using the AWS Management Console, AWS CLI, or Amazon S3 API.

Moving data to S3 Intelligent-Tiering

There are two ways to move data into S3 Intelligent-Tiering. You can upload objects directly into S3 Intelligent-Tiering from the console or programmatically using a PUT operation. For more information, see [Setting the storage class of an object](#). You can also configure S3 Lifecycle configurations to transition objects from S3 Standard or S3 Standard-Infrequent Access to S3 Intelligent-Tiering.

Uploading data to S3 Intelligent-Tiering using Direct PUT

When you upload an object to the S3 Intelligent-Tiering storage class using the [PUT](#) API operation, you specify S3 Intelligent-Tiering in the [`x-amz-storage-class`](#) request header.

The following request stores the image, `my-image.jpg`, in the `myBucket` bucket. The request uses the `x-amz-storage-class` header to request that the object is stored using the S3 Intelligent-Tiering storage class.

Example

```
PUT /my-image.jpg HTTP/1.1
Host: myBucket.s3.<Region>.amazonaws.com (http://amazonaws.com/)
Date: Wed, 1 Sep 2021 17:50:00 GMT
Authorization: authorization string
Content-Type: image/jpeg
Content-Length: 11434
Expect: 100-continue
x-amz-storage-class: INTELLIGENT_TIERING
```

Transitioning data to S3 Intelligent-Tiering from S3 Standard or S3 Standard-Infrequent Access using S3 Lifecycle

You can add rules to an S3 Lifecycle configuration to tell Amazon S3 to transition objects from one storage class to another. For information on supported transitions and related constraints, see [Transitioning objects using S3 Lifecycle](#).

You can specify S3 Lifecycle configurations at the bucket or prefix level. In this S3 Lifecycle configuration rule, the filter specifies a key prefix (`documents/`). Therefore, the rule applies to objects with key name prefix `documents/`, such as `documents/doc1.txt` and `documents/doc2.txt`. The rule specifies a Transition action directing Amazon S3 to transition objects to the S3 Intelligent-Tiering storage class 0 days after creation. In this case, objects are eligible for transition to S3 Intelligent-Tiering at midnight UTC following creation.

Example

```
<LifecycleConfiguration>
<Rule>
  <ID>ExampleRule</ID>
  <Filter>
    <Prefix>documents/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>0</Days>
    <StorageClass>INTELLIGENT_TIERING</StorageClass>
```

```
</Transition>
</Rule>
</LifecycleConfiguration>
```

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate Lifecycle rules for current and noncurrent object versions.

For more information, see [Lifecycle configuration elements](#).

Enabling S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To get the lowest storage cost on data that can be accessed in minutes to hours, you can activate one or both of the archive access tiers by creating a bucket, prefix, or object tag level configuration using the AWS Management Console, AWS CLI, or Amazon S3 API.

Using the S3 console

To enable S3 Intelligent-Tiering automatic archiving

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want.
3. Choose **Properties**.
4. Navigate to the **S3 Intelligent-Tiering Archive configurations** section and choose **Create configuration**.
5. In the **Archive configuration settings** section, specify a descriptive configuration name for your S3 Intelligent-Tiering Archive configuration.
6. Under **Choose a configuration scope**, choose a configuration scope to use. Optionally, you can limit the configuration scope to specified objects within a bucket using a shared prefix, object tag, or combination of the two.
 - a. To limit the scope of the configuration, select **Limit the scope of this configuration using one or more filters**.
 - b. To limit the scope of the configuration using a single prefix, enter the prefix under **Prefix**.
 - c. To limit the scope of the configuration using object tags, select **Add tag** and enter a value for **Key**.
7. Under **Status**, select **Enable**.

8. In the **Archive settings** section, select one or both of the Archive Access tiers to enable.
9. Choose **Create**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Intelligent-Tiering configurations:

- [delete-bucket-intelligent-tiering-configuration](#)
- [get-bucket-intelligent-tiering-configuration](#)
- [list-bucket-intelligent-tiering-configurations](#)
- [put-bucket-intelligent-tiering-configuration](#)

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the *Amazon S3 API Reference*.

When using the AWS CLI, you cannot specify the configuration as an XML file. You must specify the JSON instead. The following is an example XML S3 Intelligent-Tiering configuration and equivalent JSON that you can specify in an AWS CLI command.

The following example puts an S3 Intelligent-Tiering configuration to the specified bucket.

[Example put-bucket-intelligent-tiering-configuration](#)

JSON

```
{  
  "Id": "string",  
  "Filter": {  
    "Prefix": "string",  
    "Tag": {  
      "Key": "string",  
      "Value": "string"  
    },  
    "And": {  
      "Prefix": "string",  
      "Tags": [  
        {  
          "Key": "string",  
          "Value": "string"  
        }  
      ]  
    }  
  }  
}
```

```
    ...
  ]
}

},
>Status": "Enabled"|"Disabled",
"Tierings": [
  {
    "Days": integer,
    "AccessTier": "ARCHIVE_ACCESS"|"DEEP_ARCHIVE_ACCESS"
  }
  ...
]
}
```

XML

```
PUT /?intelligent-tiering&id=Id HTTP/1.1
Host: Bucket.s3.amazonaws.com
<?xml version="1.0" encoding="UTF-8"?>
<IntelligentTieringConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Id>string</Id>
  <Filter>
    <And>
      <Prefix>string</Prefix>
      <Tag>
        <Key>string</Key>

      </Tag>
      ...
    </And>
    <Prefix>string</Prefix>
    <Tag>
      <Key>string</Key>
      <Value>string</Value>
    </Tag>
  </Filter>
  <Status>string</Status>
  <Tiering>
    <AccessTier>string</AccessTier>
    <Days>integer</Days>
  </Tiering>
  ...
</IntelligentTieringConfiguration>
```

Using the PUT API operation

You can use the [PutBucketIntelligentTieringConfiguration](#) operation for a specified bucket and up to 1,000 S3 Intelligent-Tiering configurations per bucket. You can define which objects within a bucket are eligible for the archive access tiers using a shared prefix or object tag. Using a shared prefix or object tag allows you to align to specific business applications, workflows, or internal organizations. You also have the flexibility to activate the Archive Access tier, the Deep Archive Access tier, or both.

Getting started with S3 Intelligent-Tiering

To learn more about how to use S3 Intelligent-Tiering, see [Tutorial: Getting started using S3 Intelligent-Tiering](#).

Managing S3 Intelligent-Tiering

The S3 Intelligent-Tiering storage class delivers automatic storage cost savings in three low-latency and high-throughput access tiers. It also offers optional archive capabilities to help you get the lowest storage costs in the cloud for data that can be accessed in minutes to hours.

Identifying which S3 Intelligent-Tiering access tier objects are stored in

To get a list of your objects and their corresponding metadata, including their S3 Intelligent-Tiering access tier, you can use [Amazon S3 Inventory](#). S3 Inventory provides CSV, ORC, or Parquet output files that list your objects and their corresponding metadata. You can receive these inventory reports on either a daily or weekly basis for an Amazon S3 bucket or a shared prefix. (*Shared prefix* refers to objects that have names that begin with a common string.)

Viewing the archive status of an object within S3 Intelligent-Tiering

To receive notice when an object within the S3 Intelligent-Tiering storage class has moved to either the Archive Access tier or the Deep Archive Access tier, you can set up S3 Event Notifications. For more information, see [Enabling event notifications](#).

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:IntelligentTiering` event. For more information, see [the section called “Event message structure”](#).

```
{  
    "Records": [  
        {  
            "eventVersion": "2.3",  
            "eventSource": "aws:s3",  
            "awsRegion": "us-west-2",  
            "eventTime": "1970-01-01T00:00:00.000Z",  
            "eventName": "IntelligentTiering",  
            "userIdentity": {  
                "principalId": "s3.amazonaws.com"  
            },  
            "requestParameters": {  
                "sourceIPAddress": "s3.amazonaws.com"  
            },  
            "responseElements": {  
                "x-amz-request-id": "C3D13FE58DE4C810",  
                "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/  
JRWeUWerMUE5JgHvAN0jpD"  
            },  
            "s3": {  
                "s3SchemaVersion": "1.0",  
                "configurationId": "testConfigRule",  
                "bucket": {  
                    "name": "amzn-s3-demo-bucket",  
                    "ownerIdentity": {  
                        "principalId": "A3NL1KOZZKExample"  
                    },  
                    "arn": "arn:aws:s3:::amzn-s3-demo-bucket"  
                },  
                "object": {  
                    "key": "HappyFace.jpg",  
                    "size": 1024,  
                    "eTag": "d41d8cd98f00b204e9800998ecf8427e",  
                }  
            },  
            "intelligentTieringEventData": {  
                "destinationAccessTier": "ARCHIVE_ACCESS"  
            }  
        }  
    ]  
}
```

You can also use a [HEAD object request](#) to view an object's archive status. If an object is stored in the S3 Intelligent-Tiering storage class and is in one of the archive tiers, the HEAD object response shows the current archive tier. To show the archive tier, the request uses the [x-amz-archive-status](#) header.

The following HEAD object request returns the metadata of an object (in this case, *my-image.jpg*).

Example

```
HEAD /my-image.jpg HTTP/1.1
Host: bucket.s3.region.amazonaws.com
Date: Wed, 28 Oct 2009 22:32:00 GMT
Authorization: AWS AKIAIOSFODNN7EXAMPLE:02236Q3V0RonhpaBX5sCYVf1bNRuU=
```

You can also use HEAD object requests to monitor the status of a `restore-object` request. If the archive restoration is in progress, the HEAD object response includes the [x-amz-restore](#) header.

The following sample HEAD object response shows an object archived by using S3 Intelligent-Tiering with a restore request in progress.

Example

```
HTTP/1.1 200 OK
x-amz-id-2: FSVaTMjrmBp3Izs1NnwBZeum19ii8UbxBmi0A8AirHANJBo+hEftBuiESAC0MjP
x-amz-request-id: E5CEFCB143EB505A
Date: Fri, 13 Nov 2020 00:28:38 GMT
Last-Modified: Mon, 15 Oct 2012 21:58:07 GMT
ETag: "1accb31fcf202eba0c0f41fa2f09b4d7"
x-amz-storage-class: 'INTELLIGENT_TIERING'
x-amz-archive-status: 'ARCHIVE_ACCESS'
x-amz-restore: 'ongoing-request="true"'
x-amz-restore-request-date: 'Fri, 13 Nov 2020 00:20:00 GMT'
Accept-Ranges: bytes
Content-Type: binary/octet-stream
Content-Length: 300
Server: AmazonS3
```

Restoring objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a [restore request](#), and then wait until the object is moved into the Frequent Access

tier. For more information about archived objects, see [the section called “Working with archived objects”](#).

When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. Afterwards, if the object isn't accessed for 30 consecutive days, it automatically moves into the Infrequent Access tier. Then, after a minimum of 90 consecutive days of no access, the object moves into the Archive Access tier. After a minimum of 180 consecutive days of no access, the object moves into the Deep Archive Access tier. For more information, see [the section called “How S3 Intelligent-Tiering works”](#).

You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the Amazon S3 REST API, the AWS SDKs, or the AWS Command Line Interface (AWS CLI). For more information, see [the section called “Working with archived objects”](#).

Understanding S3 Glacier storage classes for long-term data storage

You can use Amazon S3 S3 Glacier storage classes to provide cost-effective solutions to storing long-term data that isn't accessed often. The S3 Glacier storage classes are:

- S3 Glacier Instant Retrieval
- S3 Glacier Flexible Retrieval
- S3 Glacier Deep Archive

You choose one of these storage classes based on how often you access your data and how fast you need to retrieve it. Each of these storage classes offer the same durability and resiliency as the S3 Standard storage class, but at lower storage costs. For more information about the S3 Glacier storage classes, see <https://aws.amazon.com/s3/storage-classes/glacier/>.

Topics

- [Comparing the S3 Glacier storage classes](#)
- [S3 Glacier Instant Retrieval](#)
- [S3 Glacier Flexible Retrieval](#)
- [S3 Glacier Deep Archive](#)
- [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#)
- [How these storage classes differ from the S3 Glacier service](#)

Comparing the S3 Glacier storage classes

Each S3 Glacier storage class has a minimum storage duration for all objects. If you delete, overwrite, or transition the object to a different storage class before the minimum, you are charged for the remainder of that duration.

Some S3 Glacier storage classes are archival, which means the objects stored in those classes are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#).

Storage classes designed for less frequent access patterns with longer retrieval times offer lower storage costs. For pricing information, see <https://aws.amazon.com/s3/pricing/>.

The following table summarizes the key points to consider when choosing a S3 Glacier storage class:

S3 Glacier Instant Retrieval

We recommend using S3 Glacier Instant Retrieval for long-term data that's accessed once per quarter and requires millisecond retrieval times. This storage class is ideal for performance-sensitive use cases such as image hosting, file-sharing applications, and storing medical records for access during appointments.

S3 Glacier Instant Retrieval storage class offers real-time access to your objects with the same latency and throughput performance as the S3 Standard-IA storage class. When compared to S3 Standard-IA, S3 Glacier Instant Retrieval has lower storage costs but higher data access costs.

There is a minimum object size of 128 KB for data stored in the S3 Glacier Instant Retrieval storage class. This storage class also has a minimum storage duration period of 90 days.

S3 Glacier Flexible Retrieval

We recommend using S3 Glacier Flexible Retrieval for archive data that's accessed one to two times a year and doesn't require immediate access. S3 Glacier Flexible Retrieval offers flexible retrieval times to help you balance costs, with access times ranging from a few minutes to hours, and free bulk retrievals. This storage class is ideal for backup and disaster recovery.

Objects stored in S3 Glacier Flexible Retrieval are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#). To access these objects, you first initiate a restore request which creates a

temporary copy of the object that you can access when the request completes. For information, see [Working with archived objects](#). When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Flexible Retrieval:

- **Expedited retrieval** – Typically restores the object in 1–5 minutes. Expedited retrievals are subject to demand, so to make sure you have reliable and predictable restore times, we recommend that you purchase provisioned retrieval capacity. For more information, see [Provisioned capacity](#).
- **Standard retrieval** – Typically restores the object in 3–5 hours, or within 1 minute to 5 hours when you use S3 Batch Operations. For more information, see [Restore objects with Batch Operations](#).
- **Bulk retrieval** – Typically restores the object within 5–12 hours. Bulk retrievals are free.

The minimum storage duration for objects in S3 Glacier Flexible Retrieval storage class is 90 days.

S3 Glacier Flexible Retrieval requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Flexible Retrieval. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

S3 Glacier Deep Archive

We recommend using S3 Glacier Deep Archive for archive data that's accessed less than once a year. This storage class is designed for retaining data sets for multiple years to meet compliance requirements and can also be used for backup or disaster recovery or any infrequently accessed data that you can wait up to 72 hours to retrieve. S3 Glacier Deep Archive is the lowest-cost storage option in AWS.

Objects stored in S3 Glacier Deep Archive are archived and not available for real-time access. For more information, see [Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive](#). To access these objects, you first initiate a restore request which creates a temporary copy of the object that you can access when the request completes. For information, see [Working with archived objects](#). When you restore an object, you can choose a retrieval tier to meet your use case, with lower costs for longer restore times.

The following retrieval tiers are available for S3 Glacier Deep Archive:

- **Standard retrieval** – Typically restores the object within 12 hours, or within 9–12 hours when you use S3 Batch Operations. For more information, see [Restore objects with Batch Operations](#).
- **Bulk retrieval** – Typically restores the object within 48 hours at a fraction of the cost of the Standard retrieval tier.

The minimum storage duration for objects in S3 Glacier Deep Archive storage class is 180 days.

S3 Glacier Deep Archive requires 40 KB of additional metadata for each object. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for S3 Glacier Deep Archive. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

Understanding archival storage in S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive

S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are archival storage classes. This means that when you store an object in these storage classes that object is archived, and cannot be accessed directly. To access an archived object, you submit a restore request for it, and then wait for the service to restore the object. The restore request restores a temporary copy of the object, and that copy is deleted when the duration you specified in the request expires. For more information see [Working with archived objects](#).

The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

Note

The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

You can restore archived objects in these storage classes with up to 1,000 transactions per second (TPS) of [object restore requests](#) per account per AWS Region.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – Each archived object requires 40 KB of additional metadata. This includes 32 KB of metadata required to identify and retrieve your data, which is charged at the default rate for that storage class. An additional 8 KB data is required to maintain the user-defined name and metadata for archived objects, and is charged at the S3 Standard rate.

If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.

- **Multipart upload pricing** – Objects in S3-storage-class-glacier; and S3 Glacier Deep Archive are billed at S3 Standard storage class rates when you upload them using multipart uploads. For more information, see [Multipart upload and pricing](#).
- **Minimum 30 day storage charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to these storage classes doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges for the remainder of that duration.
- **Data retrieval charges** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see [Amazon S3 pricing](#).
- **S3 Lifecycle** – When you restore an archived objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive there are per-request data retrieval charges. These charges vary based on the retrieval tier you choose when you initiate a restore. For pricing information, see [Amazon S3 pricing](#).

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A [HeadObject](#) or [GetObject](#) API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

Note

When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see [Amazon S3 pricing](#).

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see [Restoring an archived object](#).

How these storage classes differ from the S3 Glacier service

The S3 Glacier storage classes are part of the Amazon S3 service and store data as objects in S3 buckets. You can manage objects in these storage classes using the S3 console or programmatically using the S3 APIs or SDKs. When you store objects in S3 Glacier storage classes, you can use S3 features such as advanced encryption, object tagging, and S3 Lifecycle configurations to help manage data accessibility and cost.

Important

We recommend using the S3 Glacier storage classes within the Amazon S3 service for all of your long-term data.

The Amazon S3 Glacier (S3 Glacier) service is a separate service that stores data as archives within vaults. This service doesn't support Amazon S3 features and doesn't provide console support for data upload and download operations. We don't recommend using the S3 Glacier service for your long-term data. Data stored in this service isn't accessible from the Amazon S3 service. If you are

looking for information on the S3 Glacier service, see the [Amazon S3 Glacier Developer Guide](#). To transfer data from the Amazon S3 Glacier service to a storage class in Amazon S3 see [Data Transfer from Amazon S3 Glacier Vaults to Amazon S3](#) in the AWS solutions library.

Working with archived objects

To reduce your storage costs for infrequently accessed objects, you can *archive* those objects. When you archive an object, it is moved into low-cost storage, which means that you can't access it in real time.

Although archived objects are not accessible in real time, you can restore them in minutes or hours, depending on the storage class. You can restore an archived object by using the Amazon S3 console, S3 Batch Operations, the REST API, the AWS SDKs, and the AWS Command Line Interface (AWS CLI). For instructions, see [Restoring an archived object](#).

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

To restore archived objects, you must do the following:

- For objects in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, you must initiate the restore request and wait until a temporary copy of the object is available. When a temporary copy of the restored object is created, the object's storage class remains the same. (A [HeadObject](#) or [GetObject](#) API operation request returns S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)
- For objects in the S3 Intelligent-Tiering Archive Access and S3 Intelligent-Tiering Deep Archive Access tiers, you must initiate the restore request and wait until the object is moved into the Frequent Access tier.

For more information about how all Amazon S3 storage classes compare, see [Understanding and managing Amazon S3 storage classes](#). For more information about S3 Intelligent-Tiering, see [the section called "How S3 Intelligent-Tiering works"](#).

The time it takes a restore job to finish depends on which archive storage class or storage tier you use and which retrieval option you specify: Expedited (only available for S3 Glacier Flexible Retrieval and S3 Intelligent-Tiering Archive Access), Standard, or Bulk. For more information, see [Understanding archive retrieval options](#).

You can be notified when your restore is complete by using Amazon S3 Event Notifications. For more information, see [Amazon S3 Event Notifications](#).

Restoring objects from S3 Glacier

When you use S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 restores a temporary copy of the object only for the specified duration. After that, it deletes the restored object copy. You can modify the expiration period of a restored copy by reissuing a restore request. In this case, Amazon S3 updates the expiration period relative to the current time.

 **Note**

When you restore an archived object from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, you pay for both the archived object and the copy that you restored temporarily. For information about pricing, see [Amazon S3 pricing](#).

Amazon S3 calculates the expiration time of the restored object copy by adding the number of days specified in the restoration request to the time when the requested restoration is completed. Amazon S3 then rounds the resulting time to the next day at midnight Universal Coordinated Time (UTC). For example, suppose that a restored object copy was created on October 15, 2012, at 10:30 AM UTC, and the restoration period was specified as 3 days. In this case, the restored copy expires on October 19, 2012, at 00:00 UTC, at which time Amazon S3 deletes the object copy.

Restoring objects from S3 Intelligent-Tiering

When you restore an object from the S3 Intelligent-Tiering Archive tier or S3 Intelligent-Tiering Deep Archive Access tier, the object moves back into the S3 Intelligent-Tiering Frequent Access tier. If the object is not accessed after 30 consecutive days, it automatically moves into the Infrequent Access tier. After a minimum of 90 consecutive days of no access, the object moves into the S3 Intelligent-Tiering Archive Access tier. If the object is not accessed after a minimum of 180 consecutive days, the object moves into the Deep Archive Access tier.

Note

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Using S3 Batch Operations with restore requests

To restore more than one Amazon S3 object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

Topics

- [Understanding archive retrieval options](#)
- [Restoring an archived object](#)

Understanding archive retrieval options

The following are the available retrieval options when restoring an archived object in Amazon S3:

- **Expedited** – Quickly access your data that is stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. You can use this option when occasional urgent requests for a subset of archives are required. For all but the largest archived objects (250 MB+), data that is accessed by using expedited retrievals is typically made available within 1–5 minutes.

Note

Expedited retrievals are a premium feature and are charged at the Expedited request and retrieval rate.

For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

Provisioned capacity helps ensure that retrieval capacity for expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. For more information, see [Provisioned capacity](#).

- **Standard** – Access any of your archived objects within several hours. Standard is the default option for retrieval requests that do not specify the retrieval option. Standard retrievals typically finish within 3–5 hours for objects stored in the S3 Glacier Flexible Retrieval storage class or S3 Intelligent-Tiering Archive Access tier. These retrievals typically finish within 12 hours for objects stored in the S3 Glacier Deep Archive storage class or S3 Intelligent-Tiering Deep Archive Access tier. Standard retrievals are free for objects that are stored in S3 Intelligent-Tiering.

 **Note**

- For objects stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Standard retrievals initiated by using the S3 Batch Operations restore operation typically start within minutes and finish within 3–5 hours.
 - For objects in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, Standard retrievals initiated by using the Batch Operations restore operation typically start within 9 hours and finish within 12 hours.
- **Bulk** – Access your data by using the lowest-cost retrieval option in Amazon S3 Glacier. With Bulk retrievals, you can retrieve large amounts, even petabytes, of data inexpensively.

For objects that are stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier, Bulk retrievals typically finish within 5–12 hours. For objects stored in the S3 Glacier Deep Archive storage class or the S3 Intelligent-Tiering Deep Archive Access tier, these retrievals typically finish within 48 hours.

Bulk retrievals are free for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering storage classes.

The following table summarizes the archive retrieval options. For information about pricing, see [Amazon S3 pricing](#).

To make an Expedited, Standard, or Bulk retrieval, set the `Tier` request element in the [RestoreObject](#) REST API operation request to the option that you want, or the equivalent in the AWS Command Line Interface (AWS CLI) or AWS SDKs. If you purchased provisioned capacity, all Expedited retrievals are automatically served through your provisioned capacity.

Provisioned capacity

Provisioned capacity helps ensure that your retrieval capacity for Expedited retrievals from S3 Glacier Flexible Retrieval is available when you need it. Each unit of capacity provides that at least three Expedited retrievals can be performed every 5 minutes, and it provides up to 150 megabytes per second (MBps) of retrieval throughput.

If your workload requires highly reliable and predictable access to a subset of your data in minutes, consider purchasing provisioned retrieval capacity. Without provisioned capacity, Expedited retrievals might not be accepted during periods of high demand. If you require access to Expedited retrievals under all circumstances, we recommend that you purchase provisioned retrieval capacity.

Provisioned capacity units are allocated to an AWS account. Thus, the requester of the Expedited data retrieval should purchase the provisioned capacity unit, not the bucket owner.

You can purchase provisioned capacity by using the Amazon S3 console, the Amazon S3 Glacier console, the [Purchase Provisioned Capacity](#) REST API operation, the AWS SDKs, or the AWS CLI. For provisioned capacity pricing information, see [Amazon S3 pricing](#).

S3 Glacier restore initiation request rates

When you initiate restore requests for objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a retrieval-requests quota is applied for your AWS account. S3 Glacier supports restore requests at a rate of 1,000 transactions per second. If this rate is exceeded otherwise valid requests are throttled or rejected and Amazon S3 returns a `ThrottlingException` error.

Optionally, you can also use S3 Batch Operations to retrieve a large number of objects stored in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with a single request. For more information, see [Performing object operations in bulk with Batch Operations](#).

Restoring an archived object

Amazon S3 objects in the following storage classes or tiers are archived and are not accessible in real time:

- The S3 Glacier Flexible Retrieval storage class
- The S3 Glacier Deep Archive storage class
- The S3 Intelligent-Tiering Archive Access tier
- The S3 Intelligent-Tiering Deep Archive Access tier

Amazon S3 objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not immediately accessible. To access an object in these storage classes, you must restore a temporary copy of the object to its S3 bucket for a specified duration (number of days). If you want a permanent copy of the object, restore the object, and then create a copy of it in your Amazon S3 bucket. Copying restored objects isn't supported in the Amazon S3 console. For this type of copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API. Unless you make a copy and change its storage class, the object will still be stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For information about using these storage classes, see [Storage classes for rarely accessed objects](#).

To access objects in the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers, you must initiate a restore request and wait until the object is moved into the Frequent Access tier. When you restore an object from the Archive Access tier or Deep Archive Access tier, the object moves back into the Frequent Access tier. For information about using these storage classes, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).

For general information about archived objects, see [Working with archived objects](#).

Note

- When you restore an archived object from the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, you pay for both the archived object and the copy that you restored temporarily.
- When you restore an object from S3 Intelligent-Tiering, there are no retrieval charges for Standard or Bulk retrievals.
- Subsequent restore requests called on archived objects that have already been restored are billed as GET requests. For information about pricing, see [Amazon S3 pricing](#).

Restoring an archived object

You can restore an archived object by using the Amazon S3 console, the Amazon S3 REST API, the AWS SDKs, the AWS Command Line Interface (AWS CLI), or S3 Batch Operations.

Using the S3 console

Restore objects using the Amazon S3 console

Use the following procedure to Restore an object that has been archived to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes, or the S3 Intelligent-Tiering Archive Access or Deep Archive Access storage tiers.

To restore an archived object

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object or objects that you want to restore, choose **Actions**, and then choose **Initiate restore**.
5. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, enter the number of days that you want your archived data to be accessible in the **Number of days that the restored copy is available** box.
6. For **Retrieval tier**, do one of the following:
 - Choose **Bulk retrieval** or **Standard retrieval**, and then choose **Initiate restore**.
 - Choose **Expedited retrieval** (available only for S3 Glacier Flexible Retrieval or S3 Intelligent-Tiering Archive Access). If you're restoring an object in S3 Glacier Flexible Retrieval, you can choose whether to buy provisioned capacity for your Expedited retrieval. If you want to purchase provisioned capacity, proceed to the next step. If you don't, choose **Initiate restore**.

 **Note**

Objects from the S3 Intelligent-Tiering Archive Access and Deep Archive Access tiers are automatically restored to the Frequent Access tier.

7. (Optional) If you're restoring an object in S3 Glacier Flexible Retrieval and you chose **Expedited retrieval**, you can choose whether to buy provisioned capacity. Provisioned capacity is available only for objects in S3 Glacier Flexible Retrieval. If you already have provisioned capacity, choose **Initiate restore** to start a provisioned retrieval.

If you have provisioned capacity, all of your Expedited retrievals are served by your provisioned capacity. For more information, see [Provisioned capacity](#).

- If you don't have provisioned capacity and you don't want to buy it, choose **Initiate restore**.
- If you don't have provisioned capacity, but you want to buy provisioned capacity units (PCUs), choose **Purchase PCUs**. In the **Purchase PCUs** dialog box, choose how many PCUs you want to buy, confirm your purchase, and then choose **Purchase PCUs**. When you get the **Purchase succeeded** message, choose **Initiate restore** to start provisioned retrieval.

Using the AWS CLI

Restore objects from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive

The following example uses the `restore-object` command to restore the object `dir1/example.obj` in the bucket `amzn-s3-demo-bucket` for 25 days.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{"Days":25,"GlacierJobParameters":{"Tier":"Standard"}}'
```

If the JSON syntax used in the example results in an error on a Windows client, replace the restore request with the following syntax:

```
--restore-request Days=25,GlacierJobParameters={"Tier"]="Standard"}
```

Restore objects from S3 Intelligent-Tiering Archive Access and Deep Archive Access

The following example uses the `restore-object` command to restore the object `dir1/example.obj` in the bucket `amzn-s3-demo-bucket` to the Frequent Access tier.

```
aws s3api restore-object --bucket amzn-s3-demo-bucket --key dir1/example.obj --restore-request '{}'
```

Note

Unlike in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes, restore requests for S3 Intelligent-Tiering objects don't accept the Days value.

Monitor restore status

To monitor the status of your `restore-object` request, use the following `head-object` command:

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

For more information, see [restore-object](#) in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to initiate the restoration of an archived object. For more information, see [RestoreObject](#) in the *Amazon Simple Storage Service API Reference*.

Using the AWS SDKs

For examples of how to restore archived objects in S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive with the AWS SDKs, see [Code examples](#) in the *Amazon S3 API Reference*.

Using S3 Batch Operations

To restore more than one archived object with a single request, you can use S3 Batch Operations. You provide S3 Batch Operations with a list of objects to operate on. S3 Batch Operations calls the respective API operation to perform the specified operation. A single Batch Operations job can perform the specified operation on billions of objects containing exabytes of data.

To create a Batch Operations job, you must have a manifest that contains only the objects that you want to restore. You can create a manifest by using S3 Inventory, or you can supply a CSV file with the necessary information. For more information, see [the section called “Specifying a manifest”](#).

Before creating and running S3 Batch Operations jobs, you must grant permissions to Amazon S3 to perform S3 Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).

Note

Batch Operations jobs can operate either on S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage class objects *or* on S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tier objects. Batch Operations can't operate on both types of archived objects in the same job. To restore objects of both types, you *must* create separate Batch Operations jobs.

For more information about using Batch Operations to restore archive objects, see [the section called "Restore objects"](#).

To create an S3 Initiate Restore Object Batch Operations job

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Batch Operations**.
3. Choose **Create job**.
4. For **AWS Region**, choose the Region where you want to create your job.
5. Under **Manifest format**, choose the type of manifest to use.
 - If you choose **S3 inventory report**, enter the path to the manifest.json object that Amazon S3 generated as part of the CSV-formatted inventory report. If you want to use a manifest version other than the most recent, enter the version ID for the manifest.json object.
 - If you choose **CSV**, enter the path to a CSV-formatted manifest object. The manifest object must follow the format described in the console. If you want to use a version other than the most recent, you can optionally include the version ID for the manifest object.
6. Choose **Next**.
7. In the **Operation** section, choose **Restore**.
8. In the **Restore** section, for **Restore source**, choose either **Glacier Flexible Retrieval** or **Glacier Deep Archive** or **Intelligent-Tiering Archive Access tier** or **Deep Archive Access tier**.

If you chose **Glacier Flexible Retrieval** or **Glacier Deep Archive**, enter a number for **Number of days that the restored copy is available**.

For **Retrieval tier**, choose the tier that you want to use.

9. Choose **Next**.
10. On the **Configure additional options** page, fill out the following sections:
 - In the **Additional options** section, provide a description for the job and specify a priority number for the job. Higher numbers indicate a higher priority. For more information, see [the section called "Assigning job priority"](#).

- In the **Completion report** section, select whether Batch Operations should create a completion report. For more information about completion reports, see [the section called “Completion reports”](#).
- In the **Permissions** section, you must grant permissions to Amazon S3 to perform Batch Operations on your behalf. For the required permissions, see [the section called “Granting permissions”](#).
- (Optional) In the **Job tags** section, add tags in key-value pairs. For more information, see [the section called “Using tags”](#).

When you're finished, choose **Next**.

11. On the **Review** page, verify the settings. If you need to make changes, choose **Previous**. Otherwise, choose **Create job**.

For more information about Batch Operations, see [Restore objects with Batch Operations](#) and [Creating an S3 Batch Operations job](#).

Checking the restore status and expiration date

You can check the status of a restore request or the expiration date by using the Amazon S3 console, Amazon S3 Event Notifications, the AWS CLI, or the Amazon S3 REST API.

Note

Objects restored from the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are stored only for the number of days that you specify. The following procedures return the expiration date for these copies.

Objects restored from the S3 Intelligent-Tiering Archive Access and Deep Archive Access storage tiers don't have expiration dates and instead are moved back to the Frequent Access tier.

Using the S3 console

To check an object's restore status and expiration date in the Amazon S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.

3. In the buckets list, choose the name of the bucket that contains the object that you are restoring.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears.
 - If the restoration isn't finished, at the top of the page, you see a section that says **Restoration in progress**.
 - If the restoration is finished, at the top of the page, you see a section that says **Restoration complete**. If you're restoring from S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, this section also displays the **Restoration expiry date**. Amazon S3 will remove the restored copy of your archived object on this date.

Using Amazon S3 Event Notifications

You can be notified of object restoration completion by using the `s3:ObjectRestore:Completed` action with the Amazon S3 Event Notifications feature. For more information about enabling event notifications, see [Enabling notifications by using Amazon SQS, Amazon SNS, and AWS Lambda](#). For more information about the various `ObjectRestore` event types, see [the section called "Supported event types for SQS, SNS, and Lambda"](#).

Using the AWS CLI

Check an object's restore status and expiration date with the AWS CLI

The following example uses the `head-object` command to view metadata for the object `dir1/example.obj` in the bucket `amzn-s3-demo-bucket`. When you run this command on an object being restored Amazon S3 returns if the restore is ongoing and (if applicable) the expiration date.

```
aws s3api head-object --bucket amzn-s3-demo-bucket --key dir1/example.obj
```

Expected output (restore ongoing):

```
{  
  "Restore": "ongoing-request=\"true\"",  
  "LastModified": "2020-06-16T21:55:22+00:00",  
  "ContentLength": 405,  
  "ETag": "\"b662d79adec7c8d787ea7eafb9ef6207\"",  
  "VersionId": "wbYaE2vt0V0iIBXr0qGAJt3FP1cHB8Wi",  
  "ContentType": "binary/octet-stream",  
  "ServerSideEncryption": "AES256",
```

```
"Metadata": {},  
"StorageClass": "GLACIER"  
}
```

Expected output (restore finished):

```
{  
    "Restore": "ongoing-request=\"false\"", expiry-date=\"Wed, 12 Aug 2020 00:00:00 GMT  
\\\"",  
    "LastModified": "2020-06-16T21:55:22+00:00",  
    "ContentLength": 405,  
    "ETag": "\"b662d79adeb7c8d787ea7eafb9ef6207\"",  
    "VersionId": "wbYaE2vt0V0iIBXr0qGAJt3fP1cHB8Wi",  
    "ContentType": "binary/octet-stream",  
    "ServerSideEncryption": "AES256",  
    "Metadata": {},  
    "StorageClass": "GLACIER"  
}
```

For more information about `head-object`, see [head-object](#) in the *AWS CLI Command Reference*.

Using the REST API

Amazon S3 provides an API operation for you to retrieve object metadata. To check the restoration status and expiration date of an archived object using the REST API, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

Upgrading the speed of an in-progress restore

You can upgrade the speed of your restoration while it is in progress.

To upgrade an in-progress restore to a faster tier

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that contains the objects that you want to restore.
4. In the **Objects** list, select the object that you are restoring. The object's details page appears. On the object's details page, choose **Upgrade retrieval tier**. For information about checking the restoration status of an object, see [Checking the restore status and expiration date](#).

- Choose the tier that you want to upgrade to, and then choose **Initiate restore**.

Managing the lifecycle of objects

S3 Lifecycle helps you store objects cost effectively throughout their lifecycle by transitioning them to lower-cost storage classes, or, deleting expired objects on your behalf. To manage the lifecycle of your objects, create an *S3 Lifecycle configuration* for your bucket. An S3 Lifecycle configuration is a set of rules that define actions that Amazon S3 applies to a group of objects. There are two types of actions:

- Transition actions** – These actions define when objects transition to another storage class. For example, you might choose to transition objects to the S3 Standard-IA storage class 30 days after creating them, or archive objects to the S3 Glacier Flexible Retrieval storage class one year after creating them. For more information, see [Understanding and managing Amazon S3 storage classes](#).

There are costs associated with lifecycle transition requests. For pricing information, see [Amazon S3 pricing](#).

- Expiration actions** – These actions define when objects expire. Amazon S3 deletes expired objects on your behalf. For example, you might choose to expire objects after they have been stored for a regulatory compliance period. For more information, see [Expiring objects](#).

There are potential costs associated with lifecycle expiration only when you expire objects in a storage class with a minimum storage duration. For more information, see [Minimum storage duration charge](#).

Important

General purpose buckets — You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today

with an expiration action that causes objects to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old.

Changes in billing

If there is any delay between when an object becomes eligible for a lifecycle action and when Amazon S3 transfers or expires your object, billing changes are applied as soon as the object becomes eligible for the lifecycle action. For example, if an object is scheduled to expire and Amazon S3 doesn't immediately expire the object, you won't be charged for storage after the expiration time.

The one exception to this behavior is if you have a lifecycle rule to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about S3 Lifecycle rules, see [Lifecycle configuration elements](#).

Note

There are no data retrieval charges for lifecycle transitions. However, there are per-request ingestion charges when using PUT, COPY, or lifecycle rules to move data into any S3 storage class. Consider the ingestion or transition cost before moving objects into any storage class. For more information about cost considerations, see [Amazon S3 pricing](#).

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see [the section called “How do I monitor the actions taken by my lifecycle rules?”](#).

Managing the complete lifecycle of objects

With S3 Lifecycle configuration rules you can tell Amazon S3 to transition objects to less-expensive storage classes, archive or delete them. For example:

- If you upload periodic logs to a bucket, your application might need them for a week or a month. After that, you might want to delete them.
- Some documents are frequently accessed for a limited period of time. After that, they are infrequently accessed. At some point, you might not need real-time access to them, but your organization or regulations might require you to archive them for a specific period. After that, you can delete them.

- You might upload some types of data to Amazon S3 primarily for archival purposes. For example, you might archive digital media, financial, and healthcare records, raw genomics sequence data, long-term database backups, and data that must be retained for regulatory compliance.

By combining S3 Lifecycle actions to manage an object's complete lifecycle. For example, suppose that the objects you create have a well-defined lifecycle. Initially, the objects are frequently accessed for a period of 30 days. Then, objects are infrequently accessed for up to 90 days. After that, the objects are no longer needed, so you might choose to archive or delete them.

In this scenario, you can create an S3 Lifecycle rule in which you specify the initial transition action to S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage, another transition action to S3 Glacier Flexible Retrieval storage for archiving, and an expiration action. As you move the objects from one storage class to another, you save on storage costs. For more information about cost considerations, see [Amazon S3 pricing](#).

Topics

- [Lifecycle configuration elements](#)
- [How Amazon S3 handles conflicts in lifecycle configurations](#)
- [Examples of S3 Lifecycle configurations](#)
- [Troubleshooting Amazon S3 Lifecycle issues](#)

Transitioning objects using Amazon S3 Lifecycle

You can add transition actions to an S3 Lifecycle configuration to tell Amazon S3 to move objects to another Amazon S3 storage class. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#). Some examples of when you might use S3 Lifecycle configurations in this way include the following:

- When you know that objects are infrequently accessed, you might transition them to the S3 Standard-IA storage class.

- You might want to archive objects that you don't need to access in real time to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.

Note

Encrypted objects remain encrypted throughout the storage class transition process.

Supported transitions

In an S3 Lifecycle configuration, you can define rules to transition objects from one storage class to another to save on storage costs. When you don't know the access patterns of your objects, or if your access patterns are changing over time, you can transition the objects to the S3 Intelligent-Tiering storage class for automatic cost savings. For information about storage classes, see [Understanding and managing Amazon S3 storage classes](#).

Amazon S3 supports a waterfall model for transitioning between storage classes, as shown in the following diagram.

Supported lifecycle transitions

Amazon S3 supports the following lifecycle transitions between storage classes using an S3 Lifecycle configuration.

- The S3 Standard storage class to the S3 Standard-IA, S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
- The S3 Intelligent-Tiering storage class can transition to different storage classes depending on the S3 Intelligent-Tiering access tier. The following transitions are possible for each access tier.
 - Frequent Access tier or Infrequent Access tier to S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Archive Instant Access tier to S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Archive Access tier to S3 Glacier Flexible Retrieval, or S3 Glacier Deep Archive storage classes.
 - Deep Archive Access tier to S3 Glacier Deep Archive storage classes.
- The S3 One Zone-IA storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Instant Retrieval storage class to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes.
- The S3 Glacier Flexible Retrieval storage class to the S3 Glacier Deep Archive storage class.

 **Note**

For versioning enabled or versioning suspended buckets, you can't transition objects with a Pending replication status.

Constraints and considerations for transitions

Lifecycle storage class transitions have the following constraints:

Objects smaller than 128 KB will not transition by default to any storage class

Amazon S3 applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. We don't recommend transitioning objects less than 128 KB because you are charged a transition request for each object. This means, for smaller objects, the transition costs can outweigh the storage savings. For more information about transition request costs, see **Requests & data retrievals** on the **Storage & requests** tab of the [Amazon S3 pricing](#) page.

To allow smaller objects to transition, you can add an [object size filter](#) to your Lifecycle transition rules that specifies a custom minimum size (`ObjectSizeGreater Than`) or maximum size (`ObjectSizeLess Than`). For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

Note

In September 2024 Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires, you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-default-minimum-object-size` header in a [PutBucketLifecycleConfiguration](#) request.

Objects must be stored for at least 30 days before transitioning to S3 Standard-IA or S3 One Zone-IA

Before you transition objects to S3 Standard-IA or S3 One Zone-IA, you must store them for at least 30 days in Amazon S3. For example, you cannot create a Lifecycle rule to transition objects to the S3 Standard-IA storage class one day after you create them. Amazon S3 doesn't support this

transition within the first 30 days because newer objects are often accessed more frequently or deleted sooner than is suitable for S3 Standard-IA or S3 One Zone-IA storage.

Similarly, if you are transitioning noncurrent objects (in versioned buckets), you can transition only objects that are at least 30 days noncurrent to S3 Standard-IA or S3 One Zone-IA storage. For a list of minimum storage duration for all storage class, see [Comparing the Amazon S3 storage classes](#).

You are charged for transitioning objects before their minimum storage duration

Certain storage classes have a minimum object storage duration. If you transition objects out of these storage classes before the minimum duration, you are charged for the remainder of that duration. For more information on which storage classes have minimum storage durations, see [Comparing the Amazon S3 storage classes](#).

You can't create a single Lifecycle rule that transitions objects from one storage class to another before the minimum storage duration period has passed.

For example, S3 Glacier Instant Retrieval has a minimum storage duration of 90 days. You can't specify a lifecycle rule that transitions objects to S3 Glacier Instant Retrieval after 4 days, and then transitions objects to S3 Glacier Deep Archive after 20 days. In this case the S3 Glacier Deep Archive transition must occur after at least 94 days.

You can specify two rules to accomplish this, but you pay the minimum duration storage charges. For more information about cost considerations, see [Amazon S3 pricing](#).

For more information about creating a S3 Lifecycle, see [Setting an S3 Lifecycle configuration on a bucket](#).

Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival)

By using an S3 Lifecycle configuration, you can transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes for archiving.

Before you archive objects, review the following sections for relevant considerations.

General considerations

The following are the general considerations for you to consider before you archive objects:

- Encrypted objects remain encrypted throughout the storage class transition process.

- Objects that are stored in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes are not available in real time.

Archived objects are Amazon S3 objects, but before you can access an archived object, you must first restore a temporary copy of it. The restored object copy is available only for the duration that you specify in the restore request. After that, Amazon S3 deletes the temporary copy, and the object remains archived in S3 Glacier Flexible Retrieval.

You can restore an object by using the Amazon S3 console or programmatically by using the AWS SDK wrapper libraries or the Amazon S3 REST API in your code. For more information, see [Restoring an archived object](#).

- Objects that are stored in the S3 Glacier Flexible Retrieval storage class can only be transitioned to the S3 Glacier Deep Archive storage class.

You can use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Flexible Retrieval to the S3 Glacier Deep Archive storage class only. If you want to change the storage class of an object that is stored in S3 Glacier Flexible Retrieval to a storage class other than S3 Glacier Deep Archive, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, or Reduced Redundancy as the storage class.

- The transition of objects to the S3 Glacier Deep Archive storage class can go only one way.

You cannot use an S3 Lifecycle configuration rule to convert the storage class of an object from S3 Glacier Deep Archive to any other storage class. If you want to change the storage class of an archived object to another storage class, you must use the restore operation to make a temporary copy of the object first. Then use the copy operation to overwrite the object specifying S3 Standard, S3 Intelligent-Tiering, S3 Standard-IA, S3 One Zone-IA, S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Reduced Redundancy Storage as the storage class.

 **Note**

The Copy operation for restored objects isn't supported in the Amazon S3 console for objects in the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage classes. For this type of Copy operation, use the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the REST API.

The objects that are stored in the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes are visible and available only through Amazon S3. They are not available through the separate Amazon S3 Glacier service.

These are Amazon S3 objects, and you can access them only by using the Amazon S3 console or the Amazon S3 API. You cannot access the archived objects through the separate Amazon S3 Glacier console or the Amazon S3 Glacier API.

Cost considerations

If you are planning to archive infrequently accessed data for a period of months or years, the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes can reduce your storage costs. However, to ensure that the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class is appropriate for you, consider the following:

- **Storage overhead charges** – When you transition objects to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class, a fixed amount of storage is added to each object to accommodate metadata for managing the object.
 - For each object archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. Amazon S3 stores this metadata so that you can get a real-time list of your archived objects by using the Amazon S3 API. For more information, see [Get Bucket \(List Objects\)](#). You are charged S3 Standard rates for this additional storage.
 - For each object that is archived to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, Amazon S3 adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rates for this additional storage.

If you are archiving small objects, consider these storage charges. Also consider aggregating many small objects into a smaller number of large objects to reduce overhead costs.

- **Number of days you plan to keep objects archived** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are long-term archival solutions. The minimal storage duration period is 90 days for the S3 Glacier Flexible Retrieval storage class and 180 days for S3 Glacier Deep Archive. Deleting data that is archived to Amazon S3 Glacier doesn't incur charges if the objects you delete are archived for more than the minimal storage duration period. If you delete or overwrite an archived object within the minimal duration period, Amazon S3 charges a prorated

early deletion fee. For information about the early deletion fee, see the "How am I charged for deleting objects from Amazon S3 Glacier that are less than 90 days old?" question on the [Amazon S3 FAQ](#).

- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive transition request charges** – Each object that you transition to the S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive storage class constitutes one transition request. There is a cost for each such request. If you plan to transition a large number of objects, consider the request costs. If you are archiving a mix of objects that includes small objects, especially those under 128KB, we recommend using the lifecycle object size filter to filter out small objects from your transition to reduce request costs.
- **S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive data restore charges** – S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive are designed for long-term archival of data that you access infrequently. For information about data restoration charges, see the "How much does it cost to retrieve data from Amazon S3 Glacier?" question on the [Amazon S3 FAQ](#). For information about how to restore data from Amazon S3 Glacier, see [Restoring an archived object](#).

 **Note**

S3 Lifecycle transitions objects to S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive asynchronously. There might be a delay between the transition date in the S3 Lifecycle configuration rule and the date of the physical transition. In this case you are charged the default rate of the storage class you transitioned from based on the transition date specified in the rule.

The Amazon S3 product detail page provides pricing information and example calculations for archiving Amazon S3 objects. For more information, see the following topics:

- "How is my storage charge calculated for Amazon S3 objects archived to Amazon S3 Glacier?" on the [Amazon S3 FAQ](#).
- "How am I charged for deleting objects from Amazon S3 Glacier that are less than 90 days old?" on the [Amazon S3 FAQ](#).
- "How much does it cost to retrieve data from Amazon S3 Glacier?" on the [Amazon S3 FAQ](#).
- [Amazon S3 pricing](#) for storage costs for the different storage classes.

Restoring archived objects

Archived objects aren't accessible in real time. You must first initiate a restore request and then wait until a temporary copy of the object is available for the duration that you specify in the request. After you receive a temporary copy of the restored object, the object's storage class remains S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive. (A [HeadObject](#) or [GetObject](#) API operation request will return S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive as the storage class.)

Note

When you restore an archive, you are paying for both the archive (S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive rate) and a copy that you restored temporarily (S3 Standard storage rate). For information about pricing, see [Amazon S3 pricing](#).

You can restore an object copy programmatically or by using the Amazon S3 console. Amazon S3 processes only one restore request at a time per object. For more information, see [Restoring an archived object](#).

Expiring objects

You can add transition actions to an S3 Lifecycle configuration to tell Amazon S3 to delete objects at the end of their lifetime. When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 takes an **Expiration** action based on which [S3 Versioning](#) state the bucket is in:

- **Nonversioned bucket** – Amazon S3 queues the object for removal and removes it asynchronously, permanently removing the object.
- **Versioning-enabled bucket** – If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.
- **Versioning-suspended bucket** – Amazon S3 creates a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the `Expiration` action. For versioning-enabled or versioning-suspended buckets, the following applies:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the `Expiration` action to direct Amazon S3 to remove any expired object delete markers. For example, see [Removing expired object delete markers in a versioning-enabled bucket](#).
- You can use the `NoncurrentVersionExpiration` action element to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered. You can base this expiration on a certain number of days since the objects became noncurrent. In addition to the number of days, you can also provide a maximum number of noncurrent versions to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can perform the associated action on a given version. To specify the maximum number of noncurrent versions, you must also provide a `Filter` element. If you don't specify a `Filter` element, Amazon S3 generates an `InvalidRequest` error when you provide a maximum number of noncurrent versions. For more information about using the `NoncurrentVersionExpiration` action element, see [the section called “Elements to describe lifecycle actions”](#).
- Amazon S3 doesn't take any action on noncurrent versions of objects that have the S3 Object Lock configuration applied.
- For objects with a Pending replication status, Amazon S3 doesn't take any action on current or non-current versions of objects.

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

⚠ Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Important

You can't use a bucket policy to prevent deletions or transitions by an S3 Lifecycle rule. For example, even if your bucket policy denies all actions for all principals, your S3 Lifecycle configuration still functions as normal.

How to find when objects will expire

To find when the current version of an object is scheduled to expire, use the [HeadObject](#) or [GetObject](#) API operation. These API operations return response headers that provide the date and time at which the current version of the object is no longer cacheable.

Note

- There may be a delay between the expiration date and the date at which Amazon S3 removes an object. You are not charged for expiration or the storage time associated with an object that has expired.

- Before updating, disabling, or deleting Lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Cataloging and analyzing your data with S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases.

Minimum storage duration charge

If you create an S3 Lifecycle expiration rule that causes objects that have been in S3 Standard-IA or S3 One Zone-IA storage for less than 30 days to expire, you are charged for 30 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Flexible Retrieval storage for less than 90 days to expire, you are charged for 90 days. If you create a Lifecycle expiration rule that causes objects that have been in S3 Glacier Deep Archive storage for less than 180 days to expire, you are charged for 180 days.

For more information, see [Amazon S3 pricing](#).

Setting an S3 Lifecycle configuration on a bucket

You can set an Amazon S3 Lifecycle configuration on a bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API. For information about S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

To view or edit the lifecycle configuration for a directory bucket, use the AWS CLI, AWS SDKs, or the Amazon S3 REST API. For more information, see [Working with S3 Lifecycle for directory buckets](#).

In your S3 Lifecycle configuration, you use *lifecycle rules* to define actions that you want Amazon S3 to take during an object's lifetime. For example, you can define rules to transition objects to another storage class, archive objects, or expire (delete) objects after a specified period of time.

S3 Lifecycle considerations

Before you set a lifecycle configuration, note the following:

Lifecycle configuration propagation delay

When you add an S3 Lifecycle configuration to a bucket, there is usually some lag before a new or updated Lifecycle configuration is fully propagated to all the Amazon S3 systems. Expect a delay of a few minutes before the configuration fully takes effect. This delay can also occur when you delete an S3 Lifecycle configuration.

Transition or expiration delay

There's a delay between when a lifecycle rule is satisfied and when the action for the rule is completed. For example, suppose that a set of objects is expired by a lifecycle rule on January 1. Even though the expiration rule has been satisfied on January 1, Amazon S3 might not actually delete these objects until days or even weeks later. This delay occurs because S3 Lifecycle queues objects for transitions or expirations asynchronously. However, changes in billing are usually applied when the lifecycle rule is satisfied, even if the action isn't complete. For more information, see [Changes in billing](#). To monitor the effect of updates made by active lifecycle rules, see [the section called "How do I monitor the actions taken by my lifecycle rules?"](#)

Updating, disabling, or deleting lifecycle rules

When you disable or delete lifecycle rules, Amazon S3 stops scheduling new objects for deletion or transition after a small delay. Any objects that were already scheduled are unscheduled and are not deleted or transitioned.

Note

Before updating, disabling, or deleting lifecycle rules, use the LIST API operations (such as [ListObjectsV2](#), [ListObjectVersions](#), and [ListMultipartUploads](#)) or [Cataloging and analyzing your data with S3 Inventory](#) to verify that Amazon S3 has transitioned and expired eligible objects based on your use cases. If you're experiencing any issues with updating, disabling, or deleting lifecycle rules, see [Troubleshooting Amazon S3 Lifecycle issues](#).

Existing and new objects

When you add a Lifecycle configuration to a bucket, the configuration rules apply to both existing objects and objects that you add later. For example, if you add a Lifecycle configuration rule today with an expiration action that causes objects with a specific prefix to expire 30 days after creation, Amazon S3 will queue for removal any existing objects that are more than 30 days old and that have the specified prefix.

Monitoring the effect of lifecycle rules

To monitor the effect of updates made by active lifecycle rules, see [the section called “How do I monitor the actions taken by my lifecycle rules?”](#)

Changes in billing

There might be a lag between when the Lifecycle configuration rules are satisfied and when the action triggered by satisfying the rule is taken. However, changes in billing happen as soon as the Lifecycle configuration rule is satisfied, even if the action isn't yet taken.

For example, after the object expiration time, you aren't charged for storage, even if the object isn't deleted immediately. Likewise, as soon as the object transition time elapses, you're charged S3 Glacier Flexible Retrieval storage rates, even if the object isn't immediately transitioned to the S3 Glacier Flexible Retrieval storage class.

However, lifecycle transitions to the S3 Intelligent-Tiering storage class are the exception. Changes in billing don't happen until after the object has transitioned into the S3 Intelligent-Tiering storage class.

Multiple or conflicting rules

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

How to set an S3 Lifecycle configuration

You can set an Amazon S3 Lifecycle configuration on a general purpose bucket by using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), the AWS SDKs, or the Amazon S3 REST API.

For information about AWS CloudFormation templates and examples, see [Working with AWS CloudFormation templates](#) and [AWS::S3::Bucket](#) in the *AWS CloudFormation User Guide*.

Using the S3 console

You can define lifecycle rules for all objects or a subset of objects in a bucket by using a shared prefix (objects names that begin with a common string) or a tag. In your lifecycle rule, you can define actions specific to current and noncurrent object versions. For more information, see the following:

- [Managing the lifecycle of objects](#)
- [Retaining multiple versions of objects with S3 Versioning](#)

To create a lifecycle rule

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a lifecycle rule for.
4. Choose the **Management** tab, and choose **Create lifecycle rule**.
5. In **Lifecycle rule name**, enter a name for your rule.

The name must be unique within the bucket.

6. Choose the scope of the lifecycle rule:
 - To apply this lifecycle rule to *all objects with a specific prefix or tag*, choose **Limit the scope to specific prefixes or tags**.
 - To limit the scope by prefix, in **Prefix**, enter the prefix.
 - To limit the scope by tag, choose **Add tag**, and enter the tag key and value.

For more information about object name prefixes, see [Naming Amazon S3 objects](#). For more information about object tags, see [Categorizing your storage using tags](#).

- To apply this lifecycle rule to *all objects in the bucket*, choose **This rule applies to all objects in the bucket**, and then choose **I acknowledge that this rule applies to all objects in the bucket**.
7. To filter a rule by object size, you can select **Specify minimum object size**, **Specify maximum object size**, or both options.

- When you're specifying a value for **Minimum object size** or **Maximum object size**, the value must be larger than 0 bytes and up to 5 TB. You can specify this value in bytes, KB, MB, or GB.
- When you're specifying both values, the maximum object size must be larger than the minimum object size.

 **Note**

The **Minimum object size** and **Maximum object size** filters exclude the specified values. For example, if you set a filter to expire objects that have a **Minimum object size** of 128 KB, objects that are exactly 128 KB don't expire. Instead, the rule applies only to objects that are greater than 128 KB in size.

8. Under **Lifecycle rule actions**, choose the actions that you want your lifecycle rule to perform:

- Transition *current* versions of objects between storage classes
- Transition *previous* versions of objects between storage classes
- Expire *current* versions of objects

 **Note**

For buckets that don't have [S3 Versioning](#) enabled, expiring current versions causes Amazon S3 to permanently delete the objects. For more information, see [the section called "Lifecycle actions and bucket versioning state"](#).

- Permanently delete *previous* versions of objects
- Delete expired delete markers or incomplete multipart uploads

Depending on the actions that you choose, different options appear.

9. To transition *current* versions of objects between storage classes, under **Transition current versions of objects between storage classes**, do the following:

- a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see [the section called "Supported lifecycle transitions"](#). You can choose from the following storage classes:

- S3 Standard-IA
 - S3 Intelligent-Tiering
 - S3 One Zone-IA
 - S3 Glacier Instant Retrieval
 - S3 Glacier Flexible Retrieval
 - S3 Glacier Deep Archive
- b. In **Days after object creation**, enter the number of days after creation to transition the object.

For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#). You can define transitions for current or previous object versions or for both current and previous versions. Versioning enables you to keep multiple versions of an object in one bucket. For more information about versioning, see [Using the S3 console](#).

 **Important**

When you choose the S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, or Glacier Deep Archive storage class, your objects remain in Amazon S3. You cannot access them directly through the separate Amazon S3 Glacier service. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).

10. To transition *noncurrent* versions of objects between storage classes, under **Transition noncurrent versions of objects between storage classes**, do the following:
- a. In **Storage class transitions**, choose the storage class to transition to. For a list of possible transitions, see [the section called "Supported lifecycle transitions"](#). You can choose from the following storage classes:
- S3 Standard-IA
 - S3 Intelligent-Tiering
 - S3 One Zone-IA
 - S3 Glacier Instant Retrieval
 - S3 Glacier Flexible Retrieval
 - S3 Glacier Deep Archive

- b. In **Days after object becomes noncurrent**, enter the number of days after creation to transition the object.
11. To expire *current* versions of objects, under **Expire current versions of objects**, in **Number of days after object creation**, enter the number of days.

⚠ Important

In a nonversioned bucket, the expiration action results in Amazon S3 permanently removing the object. For more information about lifecycle actions, see [Elements to describe lifecycle actions](#).

12. To permanently delete previous versions of objects, under **Permanently delete noncurrent versions of objects**, in **Days after objects become noncurrent**, enter the number of days. You can optionally specify the number of newer versions to retain by entering a value under **Number of newer versions to retain**.
13. Under **Delete expired delete markers or incomplete multipart uploads**, choose **Delete expired object delete markers** and **Delete incomplete multipart uploads**. Then, enter the number of days after the multipart upload initiation that you want to end and clean up incomplete multipart uploads.

For more information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

14. Choose **Create rule**.

If the rule does not contain any errors, Amazon S3 enables it, and you can see it on the **Management** tab under **Lifecycle rules**.

Using the AWS CLI

You can use the following AWS CLI commands to manage S3 Lifecycle configurations:

- `put-bucket-lifecycle-configuration`
- `get-bucket-lifecycle-configuration`
- `delete-bucket-lifecycle`

For instructions on setting up the AWS CLI, see [Developing with Amazon S3 using the AWS CLI](#) in the [Amazon S3 API Reference](#).

The Amazon S3 Lifecycle configuration is an XML file. But when you're using the AWS CLI, you cannot specify the XML format. You must specify the JSON format instead. The following are example XML lifecycle configurations and the equivalent JSON configurations that you can specify in an AWS CLI command.

Consider the following example S3 Lifecycle configuration.

Example Example 1

Example

XML

```
<LifecycleConfiguration>
  <Rule>
    <ID>ExampleRule</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>3650</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

JSON

```
{
  "Rules": [
    {
      "Filter": {
        "Prefix": "documents/"
      },
      "Status": "Enabled",
```

```
    "Transitions": [
        {
            "Days": 365,
            "StorageClass": "GLACIER"
        }
    ],
    "Expiration": {
        "Days": 3650
    },
    "ID": "ExampleRule"
}
]
```

Example Example 2

Example

XML

```
<LifecycleConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <Rule>
        <ID>id-1</ID>
        <Expiration>
            <Days>1</Days>
        </Expiration>
        <Filter>
            <And>
                <Prefix>myprefix</Prefix>
                <Tag>
                    <Key>mytagkey1</Key>
                    <Value>mytagvalue1</Value>
                </Tag>
                <Tag>
                    <Key>mytagkey2</Key>
                    <Value>mytagvalue2</Value>
                </Tag>
            </And>
        </Filter>
        <Status>Enabled</Status>
    </Rule>
</LifecycleConfiguration>
```

JSON

```
{  
    "Rules": [  
        {  
            "ID": "id-1",  
            "Filter": {  
                "And": [  
                    {"Prefix": "myprefix",  
                     "Tags": [  
                        {  
                            "Value": "mytagvalue1",  
                            "Key": "mytagkey1"  
                        },  
                        {  
                            "Value": "mytagvalue2",  
                            "Key": "mytagkey2"  
                        }  
                    ]  
                }  
            },  
            "Status": "Enabled",  
            "Expiration": {  
                "Days": 1  
            }  
        }  
    ]  
}
```

You can test the put-bucket-lifecycle-configuration as follows.

To test the configuration

1. Save the JSON Lifecycle configuration in a file (for example, *lifecycle.json*).
2. Run the following AWS CLI command to set the Lifecycle configuration on your bucket.
Replace the *user input placeholders* with your own information.

```
$ aws s3api put-bucket-lifecycle-configuration \  
--bucket amzn-s3-demo-bucket \  
--lifecycle-configuration file:///lifecycle.json
```

3. To verify, retrieve the S3 Lifecycle configuration by using the `get-bucket-lifecycle-configuration` AWS CLI command as follows:

```
$ aws s3api get-bucket-lifecycle-configuration \
--bucket amzn-s3-demo-bucket
```

4. To delete the S3 Lifecycle configuration, use the `delete-bucket-lifecycle` AWS CLI command as follows:

```
aws s3api delete-bucket-lifecycle \
--bucket amzn-s3-demo-bucket
```

Using the AWS SDKs

Java

You can use the AWS SDK for Java to manage the S3 Lifecycle configuration of a bucket. For more information about managing S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

When you add an S3 Lifecycle configuration to a bucket, Amazon S3 replaces the bucket's current Lifecycle configuration, if there is one. To update a configuration, you retrieve it, make the desired changes, and then add the revised configuration to the bucket.

The following example shows how to use the AWS SDK for Java to add, update, and delete the Lifecycle configuration of a bucket. The example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing configuration.
- Retrieves the configuration again and verifies that it has the right number of rules by printing the number of rules.

- Deletes the Lifecycle configuration and verifies that it has been deleted by attempting to retrieve it again.

For instructions on creating and testing a working sample, see [Getting Started](#) in the *AWS SDK for Java Developer Guide*.

                                "expire_after",
                                "ten_years"))))))
                                .withExpirationInDays(3650)

.withStatus(BucketLifecycleConfiguration.ENABLED));

        // Save the configuration.
s3Client.setBucketLifecycleConfiguration(bucketName,
configuration);

        // Retrieve the configuration.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);

        // Verify that the configuration now has three rules.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);
System.out.println("Expected # of rules = 3; found: " +
configuration.getRules().size());

        // Delete the configuration.
s3Client.deleteBucketLifecycleConfiguration(bucketName);

        // Verify that the configuration has been deleted by
attempting to retrieve it.
configuration =
s3Client.getBucketLifecycleConfiguration(bucketName);
String s = (configuration == null) ? "No configuration
found." : "Configuration found.";
System.out.println(s);
} catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3
couldn't process
        // it, so it returned an error response.
```

```
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the
client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

.NET

You can use the AWS SDK for .NET to manage the S3 Lifecycle configuration on a bucket. For more information about managing Lifecycle configuration, see [Managing the lifecycle of objects](#).

Note

When you add a Lifecycle configuration, Amazon S3 replaces the existing configuration on the specified bucket. To update a configuration, you must first retrieve the Lifecycle configuration, make the changes, and then add the revised Lifecycle configuration to the bucket.

The following example shows how to use the AWS SDK for .NET to add, update, and delete a bucket's Lifecycle configuration. The code example does the following:

- Adds a Lifecycle configuration to a bucket.
- Retrieves the Lifecycle configuration and updates it by adding another rule.
- Adds the modified Lifecycle configuration to the bucket. Amazon S3 replaces the existing Lifecycle configuration.
- Retrieves the configuration again and verifies it by printing the number of rules in the configuration.
- Deletes the Lifecycle configuration and verifies the deletion.

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;

```

```
}
```

Ruby

You can use the AWS SDK for Ruby to manage an S3 Lifecycle configuration on a bucket by using the class [AWS::S3::BucketLifecycleConfiguration](#). For more information about managing S3 Lifecycle configuration, see [Managing the lifecycle of objects](#).

Using the REST API

The following topics in the *Amazon Simple Storage Service API Reference* describe the REST API operations related to S3 Lifecycle configuration:

- [PutBucketLifecycleConfiguration](#)
- [GetBucketLifecycleConfiguration](#)
- [DeleteBucketLifecycle](#)

Troubleshooting S3 Lifecycle

For common issues that might occur when working with S3 Lifecycle, see [the section called "Troubleshooting lifecycle issues"](#).

How S3 Lifecycle interacts with other bucket configurations

In addition to S3 Lifecycle configurations, you can associate other configurations with your bucket. This section explains how S3 Lifecycle configuration relates to other bucket configurations.

S3 Lifecycle and S3 Versioning

You can add S3 Lifecycle configurations to unversioned buckets and versioning-enabled buckets. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

A versioning-enabled bucket maintains one current object version, and zero or more noncurrent object versions. You can define separate lifecycle rules for current and noncurrent object versions.

For more information, see [Lifecycle configuration elements](#).

⚠ Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both a S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

S3 Lifecycle configuration on MFA-enabled buckets

S3 Lifecycle configuration on multi-factor authentication (MFA)-enabled buckets isn't supported.

S3 Lifecycle and logging

Amazon S3 Lifecycle actions aren't captured by AWS CloudTrail object level logging. CloudTrail captures API requests made to external Amazon S3 endpoints, whereas S3 Lifecycle actions are performed by using internal Amazon S3 endpoints.

You can enable Amazon S3 server access logs in an S3 bucket to capture S3 Lifecycle-related actions, such as object transitions to another storage class and object expirations that result in permanent deletion or logical deletion. For more information, see [the section called "Logging server access"](#).

If you have logging enabled on your bucket, Amazon S3 server access logs report the results of the following operations.

Operation log	Description
S3.EXPIRE.OBJECT	Amazon S3 permanently deletes the object because of the lifecycle <code>Expiration</code> action.

Operation log	Description
S3.CREATE.DELETEMARKER	Amazon S3 logically deletes the current version by adding a delete marker in a versioning-enabled bucket.
S3.TRANSITION_SIA.OBJECT	Amazon S3 transitions the object to the S3 Standard-IA storage class.
S3.TRANSITION_ZIA.OBJECT	Amazon S3 transitions the object to the S3 One Zone-IA storage class.
S3.TRANSITION_INT.OBJECT	Amazon S3 transitions the object to the S3 Intelligent-Tiering storage class.
S3.TRANSITION_GIR.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Instant Retrieval storage class.
S3.TRANSITION.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Flexible Retrieval storage class.
S3.TRANSITION_GDA.OBJECT	Amazon S3 initiates the transition of the object to the S3 Glacier Deep Archive storage class.
S3.DELETE.UPLOAD	Amazon S3 aborts an incomplete multipart upload.

 **Note**

Amazon S3 server access log records are delivered on a best-effort basis and can't be used for a complete accounting of all Amazon S3 requests.

Configuring S3 Lifecycle event notifications

To receive notice when Amazon S3 deletes an object or transitions it to another Amazon S3 storage class as the result of following an S3 Lifecycle rule, you can set up an Amazon S3 event notification.

You can receive notifications for the following S3 Lifecycle events:

- **Transition events** – By using the `s3:LifecycleTransition` event type, you can receive notification when an object is transitioned from one Amazon S3 storage class to another by an S3 Lifecycle configuration.
- **Expiration (delete) events** – By using the `LifecycleExpiration` event types, you can receive notifications whenever Amazon S3 deletes an object based on your S3 Lifecycle configuration.

There are two expiration event types:

- The `s3:LifecycleExpiration:Delete` event type notifies you when an object in an unversioned bucket is deleted. `s3:LifecycleExpiration:Delete` also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration.
- The `s3:LifecycleExpiration:DeleteMarkerCreated` event type notifies you when S3 Lifecycle creates a delete marker after a current version of an object in a versioned bucket is deleted. For more information, see [the section called “Deleting object versions”](#).

Amazon S3 can publish event notifications to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

For instructions on how to configure Amazon S3 Event Notifications, see [Enabling event notifications by using Amazon SQS, Amazon SNS, and AWS Lambda](#).

The following is an example of a message that Amazon S3 sends to publish an `s3:LifecycleExpiration:Delete` event. For more information, see [the section called “Event message structure”](#).

```
{  
  "Records": [  
    {  
      "eventVersion": "2.3",  
      "eventSource": "aws:s3",  
      "awsRegion": "us-east-1",  
      "s3": {  
        "approximateCreationDate": "1970-01-01T00:00:00.000Z",  
        "bucket": "my-bucket",  
        "objectKey": "my-object-key",  
        "size": 1000  
      }  
    }  
  ]  
}
```

```
"awsRegion":"us-west-2",
"eventTime":"1970-01-01T00:00:00.000Z",
"eventName":"LifecycleExpiration:Delete",
"userIdentity":{
    "principalId":"s3.amazonaws.com"
},
"requestParameters":{
    "sourceIPAddress":"s3.amazonaws.com"
},
"responseElements":{
    "x-amz-request-id":"C3D13FE58DE4C810",
    "x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpD"
},
"s3":{
    "s3SchemaVersion":"1.0",
    "configurationId":"testConfigRule",
    "bucket": {
        "name":"amzn-s3-demo-bucket",
        "ownerIdentity": {
            "principalId":"A3NL1K0ZZKExample"
        },
        "arn":"arn:aws:s3:::amzn-s3-demo-bucket"
    },
    "object": {
        "key":"expiration/delete",
        "sequencer":"0055AED6DCD90281E5",
    }
}
}
]
```

Messages that Amazon S3 sends to publish an `s3:LifecycleTransition` event also include the following information:

```
"lifecycleEventData": {
    "transitionEventData": {
        "destinationStorageClass": the destination storage class for the object
    }
}
```

Lifecycle configuration elements

A S3 Lifecycle configuration consist of Lifecycle rules that include various elements that describe the actions Amazon S3 takes during an objects lifetime. You specify an Amazon S3 Lifecycle configuration as XML, consisting of one or more Lifecycle rules, where each rule consists of one or more elements.

```
<LifecycleConfiguration>
  <Rule>
    <Element>
  </Rule>
  <Rule>
    <Element>
    <Element>
  </Rule>
</LifecycleConfiguration>
```

Each rule consists of the following:

- Rule metadata that includes a rule ID, and a status that indicates whether the rule is enabled or disabled. If a rule is disabled, Amazon S3 doesn't perform any actions specified in the rule.
- A filter that identifies the objects to which the rule applies. You can specify a filter by using the object size, the object key prefix, one or more object tags, or a combination of filters.
- One or more transition or expiration actions with a date or a time period in the object's lifetime when you want Amazon S3 to perform the specified action.

Topics

- [ID element](#)
- [Status element](#)
- [Filter element](#)
- [Elements to describe lifecycle actions](#)
- [Adding filters to Lifecycle rules](#)

The following sections describe the XML elements in an S3 Lifecycle configuration. For example configurations, see [Examples of S3 Lifecycle configurations](#).

ID element

An S3 Lifecycle configuration can have up to 1,000 rules. This limit is not adjustable. The <ID> element uniquely identifies a rule. ID length is limited to 255 characters.

Status element

The <Status> element value can be either Enabled or Disabled. If a rule is disabled, Amazon S3 doesn't perform any of the actions defined in the rule.

Filter element

A S3 Lifecycle rule can apply to all or a subset of objects in a bucket based on the <Filter> element that you specify in the rule.

You can filter objects by key prefix, object tags, or a combination of both (in which case Amazon S3 uses a logical AND to combine the filters). For examples and more information about filters see, [Adding filters to Lifecycle rules](#).

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to the objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
  ...
</LifecycleConfiguration>
```

If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes projectA/ and projectB/, you specify two rules as follows:

```
<LifecycleConfiguration>
```

```
<Rule>
  <Filter>
    <Prefix>projectA/</Prefix>
  </Filter>
  transition/expiration actions
  ...
</Rule>

<Rule>
  <Filter>
    <Prefix>projectB/</Prefix>
  </Filter>
  transition/expiration actions
  ...
</Rule>
</LifecycleConfiguration>
```

For more information about object keys, see [Naming Amazon S3 objects](#).

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Tag>
        <Key>key</Key>
        <Value>value</Value>
      </Tag>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the `<And>` element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
  <Rule>
```

```
<Filter>
  <And>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
    ...
  </And>
</Filter>
transition/expiration actions
</Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a `<Key>` element and no `<Value>` element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

 **Note**

When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the `<And>` element, as follows:

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <Tag>
          <Key>key1</Key>
```

```
<Value>value1</Value>
</Tag>
<Tag>
  <Key>key2</Key>
  <Value>value2</Value>
</Tag>
...
</And>
</Filter>
<Status>Enabled</Status>
transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- You can specify an **empty filter**, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
<Rule>
  <Filter>
  </Filter>
  <Status>Enabled</Status>
  transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

- To filter a rule by **object size**, you can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLess Than`), or you can specify a range of object sizes.

Object size values are in bytes. By default, objects smaller than 128 KB will not be transitioned to any storage class, unless you specify a smaller minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLess Than`). For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

```
<LifecycleConfiguration>
<Rule>
  <Filter>
    <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
```

```
</Filter>
<Status>Enabled</Status>
transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

Note

The `ObjectSizeGreater Than` and `ObjectSizeLess Than` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreater Than` integer must be less than the `ObjectSizeLess Than` value. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <ObjectSizeGreater Than>500</ObjectSizeGreater Than>
        <ObjectSizeLess Than>64000</ObjectSizeLess Than>
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

Elements to describe lifecycle actions

You can direct Amazon S3 to perform specific actions in an object's lifetime by specifying one or more of the following predefined actions in an S3 Lifecycle rule. The effect of these actions depends on the versioning state of your bucket.

- **Transition action element** – You specify the Transition action to transition objects from one storage class to another. For more information about transitioning objects, see [Supported transitions](#). When a specified date or time period in the object's lifetime is reached, Amazon S3 performs the transition.

For a versioned bucket (versioning-enabled or versioning-suspended bucket), the Transition action applies to the current object version. To manage noncurrent versions, Amazon S3 defines the NoncurrentVersionTransition action (described later in this topic).

- **Expiration action element** – The Expiration action expires objects identified in the rule and applies to eligible objects in any of the Amazon S3 storage classes. For more information about storage classes, see [Understanding and managing Amazon S3 storage classes](#). Amazon S3 makes all expired objects unavailable. Whether the objects are permanently removed depends on the versioning state of the bucket.
 - **Nonversioned bucket** – The Expiration action results in Amazon S3 permanently removing the object.
 - **Versioned bucket** – For a versioned bucket (that is, versioning-enabled or versioning-suspended), there are several considerations that guide how Amazon S3 handles the Expiration action. For versioning-enabled or versioning-suspended buckets, the following applies:
 - The Expiration action applies only to the current version (it has no impact on noncurrent object versions).
 - Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
 - If the current object version is the only object version and it is also a delete marker (also referred as an *expired object delete marker*, where all object versions are deleted and you only have a delete marker remaining), Amazon S3 removes the expired object delete marker. You can also use the expiration action to direct Amazon S3 to remove any expired object delete markers. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Also consider the following when setting up Amazon S3 to manage expiration:

- **Versioning-enabled bucket**

If the current object version is not a delete marker, Amazon S3 adds a delete marker with a unique version ID. This makes the current version noncurrent, and the delete marker the current version.

- **Versioning-suspended bucket**

In a versioning-suspended bucket, the expiration action causes Amazon S3 to create a delete marker with null as the version ID. This delete marker replaces any object version with a null version ID in the version hierarchy, which effectively deletes the object.

In addition, Amazon S3 provides the following actions that you can use to manage noncurrent object versions in a versioned bucket (that is, versioning-enabled and versioning-suspended buckets).

- **NoncurrentVersionTransition action element** – Use this action to specify when Amazon S3 transitions objects to the specified storage class. You can base this transition on a certain number of days since the objects became noncurrent (`<NoncurrentDays>`). In addition to the number of days, you can also specify the number of noncurrent versions (`<NewerNoncurrentVersions>`) to retain (between 1 and 100). This value determines how many newer noncurrent versions must exist before Amazon S3 can transition a given version. Amazon S3 will transition any additional noncurrent versions beyond the specified number to retain. For the transition to occur, both the `<NoncurrentDays>` and the `<NewerNoncurrentVersions>` values must be exceeded.

To specify the number of noncurrent versions to retain, you must also provide a `<Filter>` element. If you don't specify a `<Filter>` element, Amazon S3 generates an `InvalidRequest` error when you specify the number of noncurrent versions to retain.

For more information about transitioning objects, see [Supported transitions](#). For details about how Amazon S3 calculates the date when you specify the number of days in the `NoncurrentVersionTransition` action, see [Lifecycle rules: Based on an object's age](#).

- **NoncurrentVersionExpiration action element** – Use this action to direct Amazon S3 to permanently delete noncurrent versions of objects. These deleted objects can't be recovered.

You can base this expiration on a certain number of days since the objects became noncurrent (<NoncurrentDays>). In addition to the number of days, you can also specify the number of noncurrent versions (<NewerNoncurrentVersions>) to retain (between 1 and 100). This value specifies how many newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the <NoncurrentDays> **and** the <NewerNoncurrentVersions> values must be exceeded.

To specify the number of noncurrent versions to retain, you must also provide a <Filter> element. If you don't specify a <Filter> element, Amazon S3 generates an InvalidRequest error when you specify the number of noncurrent versions to retain.

Delayed removal of noncurrent objects can be helpful when you need to correct any accidental deletes or overwrites. For example, you can configure an expiration rule to delete noncurrent versions five days after they become noncurrent. For example, suppose that on 1/1/2014 at 10:30 AM UTC, you create an object called photo.gif (version ID 111111). On 1/2/2014 at 11:30 AM UTC, you accidentally delete photo.gif (version ID 111111), which creates a delete marker with a new version ID (such as version ID 4857693). You now have five days to recover the original version of photo.gif (version ID 111111) before the deletion is permanent. On 1/8/2014 at 00:00 UTC, the Lifecycle rule for expiration runs and permanently deletes photo.gif (version ID 111111), five days after it became a noncurrent version.

For details about how Amazon S3 calculates the date when you specify the number of days in an NoncurrentVersionExpiration action, see [Lifecycle rules: Based on an object's age](#).

 **Note**

Object expiration lifecycle configurations don't remove incomplete multipart uploads. To remove incomplete multipart uploads, you must use the AbortIncompleteMultipartUpload Lifecycle configuration action that's described later in this section.

In addition to the transition and expiration actions, you can use the following Lifecycle configuration actions to direct Amazon S3 to stop incomplete multipart uploads or to remove expired object delete markers:

- **AbortIncompleteMultipartUpload action element** – Use this element to set a maximum time (in days) that you want to allow multipart uploads to remain in progress. If the applicable multipart uploads (determined by the key name prefix specified in the Lifecycle rule) aren't successfully completed within the predefined time period, Amazon S3 stops the incomplete multipart uploads. For more information, see [Aborting a multipart upload](#).

 **Note**

You can't specify this lifecycle action in a rule that has a filter that uses object tags.

- **ExpiredObjectDeleteMarker action element** – In a versioning-enabled bucket, a delete marker with zero noncurrent versions is referred to as an *expired object delete marker*. You can use this lifecycle action to direct Amazon S3 to remove expired object delete markers. For an example, see [Removing expired object delete markers in a versioning-enabled bucket](#).

 **Note**

You can't specify this lifecycle action in a rule that has a filter that uses object tags.

How Amazon S3 calculates how long an object has been noncurrent

In a versioning-enabled bucket, you can have multiple versions of an object. There is always one current version, and zero or more noncurrent versions. Each time you upload an object, the current version is retained as the noncurrent version and the newly added version, the successor, becomes the current version. To determine the number of days an object is noncurrent, Amazon S3 looks at when its successor was created. Amazon S3 uses the number of days since its successor was created as the number of days an object is noncurrent.

 **Restoring previous versions of an object when using S3 Lifecycle configurations**

As explained in [Restoring previous versions](#), you can use either of the following two methods to retrieve previous versions of an object:

- **Method 1 – Copy a noncurrent version of the object into the same bucket.** The copied object becomes the current version of that object, and all object versions are preserved.

- **Method 2 – Permanently delete the current version of the object.** When you delete the current object version, you, in effect, turn the noncurrent version into the current version of that object.

When you're using S3 Lifecycle configuration rules with versioning-enabled buckets, we recommend as a best practice that you use Method 1.

S3 Lifecycle operates under an eventually consistent model. A current version that you permanently deleted might not disappear until the changes propagate to all of the Amazon S3 systems. (Therefore, Amazon S3 might be temporarily unaware of this deletion.) In the meantime, the lifecycle rule that you configured to expire noncurrent objects might permanently remove noncurrent objects, including the one that you want to restore. So, copying the old version, as recommended in Method 1, is the safer alternative.

Lifecycle actions and bucket versioning state

Lifecycle rules: Based on an object's age

You can specify a time period, in the number of days from the creation (or modification) of the object, when Amazon S3 can take the specified action.

When you specify the number of days in the Transition and Expiration actions in an S3 Lifecycle configuration, note the following:

- The value that you specify is the number of days since object creation when the action will occur.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the object creation time and rounding the resulting time to the next day at midnight UTC. For example, if an object was created on 1/15/2014 at 10:30 AM UTC and you specify 3 days in a transition rule, then the transition date of the object would be calculated as 1/19/2014 00:00 UTC.

Note

Amazon S3 maintains only the last modified date for each object. For example, the Amazon S3 console shows the **Last modified** date in the object's **Properties** pane. When you initially create a new object, this date reflects the date that the object is created. If you replace the object, the date changes accordingly. Therefore, the creation date is synonymous with the **Last modified** date.

When specifying the number of days in the `NoncurrentVersionTransition` and `NoncurrentVersionExpiration` actions in a Lifecycle configuration, note the following:

- The value that you specify is the number of days from when the version of the object becomes noncurrent (that is, when the object is overwritten or deleted) that Amazon S3 will perform the action on the specified object or objects.
- Amazon S3 calculates the time by adding the number of days specified in the rule to the time when the new successor version of the object is created and rounding the resulting time to the next day at midnight UTC. For example, in your bucket, suppose that you have a current version of an object that was created on 1/1/2014 at 10:30 AM UTC. If the new version of the object that replaces the current version is created on 1/15/2014 at 10:30 AM UTC, and you specify 3 days in a transition rule, the transition date of the object is calculated as 1/19/2014 00:00 UTC.

Lifecycle rules: Based on a specific date

When specifying an action in an S3 Lifecycle rule, you can specify a date when you want Amazon S3 to take the action. When the specific date arrives, Amazon S3 applies the action to all qualified objects (based on the filter criteria).

If you specify an S3 Lifecycle action with a date that is in the past, all qualified objects become immediately eligible for that lifecycle action.

Important

The date-based action is not a one-time action. Amazon S3 continues to apply the date-based action even after the date has passed, as long as the rule status is Enabled.

For example, suppose that you specify a date-based `Expiration` action to delete all objects (assume that no filter is specified in the rule). On the specified date, Amazon S3 expires all the objects in the bucket. Amazon S3 also continues to expire any new objects that you create in the bucket. To stop the lifecycle action, you must either remove the action from the lifecycle rule, disable the rule, or delete the rule from the lifecycle configuration.

The date value must conform to the ISO 8601 format. The time is always midnight UTC.

Note

You can't create date-based Lifecycle rules by using the Amazon S3 console, but you can view, disable, or delete such rules.

Adding filters to Lifecycle rules

Filters are an optional Lifecycle rule element that you can use to specify which objects that the rule applies to.

The following elements can be used to filter objects:

Key prefix

You can filter objects based on a prefix. If you want to apply lifecycle actions a subset of objects under to more than one prefix you can specify separate rules. In each rule, specify a prefix-based filter. For more information see [example]

Object tags

You can filter objects based on one or more tags. Each tag must match both the key and value exactly, and, if you specify multiple tags each tag key must be unique. A filter with multiple object tags applies to a subset of objects that has all the tags specified. If an object has additional tags specified, the filter will still apply.

Note

If you specify only a Key element and no Value element, the rule will apply only to objects that match the tag key and that do not have a value specified.

Minimum or maximum object size

You can filter objects based on size. You can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes in the same filter. Object size values are in bytes. Maximum filter size is 5 TB. Amazon S3 applies a default minimum object size to lifecycle configuration. For more information, see [Example: Allowing objects smaller than 128 KB to be transitioned](#).

You can combine different filter elements in which case Amazon S3 uses a logical AND.

Filter examples

The following examples show how you can use different filter elements:

- **Specifying a filter by using key prefixes** – This example shows an S3 Lifecycle rule that applies to a subset of objects based on the key name prefix (logs/). For example, the Lifecycle rule applies to the objects logs/mylog.txt, logs/temp1.txt, and logs/test.txt. The rule does not apply to the object example.jpg.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
  ...
</LifecycleConfiguration>
```

Note

If you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/
  sales2000/
  sales2001/
```

To include all three prefixes in your rule, specify sales as the prefix in your lifecycle rule.

If you want to apply a lifecycle action to a subset of objects based on different key name prefixes, specify separate rules. In each rule, specify a prefix-based filter. For example, to describe a lifecycle action for objects with the key prefixes projectA/ and projectB/, you specify two rules as follows:

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Prefix>projectA/</Prefix>
    </Filter>
    transition/expiration actions
    ...
  </Rule>

  <Rule>
    <Filter>
      <Prefix>projectB/</Prefix>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
</LifecycleConfiguration>
```

For more information about object keys, see [Naming Amazon S3 objects](#).

- **Specifying a filter based on object tags** – In the following example, the Lifecycle rule specifies a filter based on a tag (*key*) and value (*value*). The rule then applies only to a subset of objects with the specific tag.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <Tag>
        <Key>key</Key>
        <Value>value</Value>
      </Tag>
    </Filter>
    transition/expiration actions
    ...
  </Rule>
</LifecycleConfiguration>
```

You can specify a filter based on multiple tags. You must wrap the tags in the `<And>` element, as shown in the following example. The rule directs Amazon S3 to perform lifecycle actions on objects with two tags (with the specific tag key and value).

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Tag>
          <Key>key1</Key>
          <Value>value1</Value>
        </Tag>
        <Tag>
          <Key>key2</Key>
          <Value>value2</Value>
        </Tag>
        ...
      </And>
    </Filter>
    transition/expiration actions
  </Rule>
</Lifecycle>
```

The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a `<Key>` element and no `<Value>` element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

 **Note**

When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the `<And>` element, as follows:

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
```

```
<Prefix>key-prefix</Prefix>
<Tag>
  <Key>key1</Key>
  <Value>value1</Value>
</Tag>
<Tag>
  <Key>key2</Key>
  <Value>value2</Value>
</Tag>
...
</And>
</Filter>
<Status>Enabled</Status>
transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- **Specifying an empty filter** – You can specify an empty filter, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

- **>Specifying an object size filter** – To filter a rule by object size, you can specify a minimum size (`ObjectSizeGreater Than`) or a maximum size (`ObjectSizeLess Than`), or you can specify a range of object sizes.

Object size values are in bytes. Maximum filter size is 5 TB. Some storage classes have minimum object size limitations. For more information, see [Comparing the Amazon S3 storage classes](#).

```
<LifecycleConfiguration>
  <Rule>
```

```
<Filter>
  <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
</Filter>
<Status>Enabled</Status>
transition/expiration actions
</Rule>
</LifecycleConfiguration>
```

Note

The `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreaterThan` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
  <Rule>
    <Filter>
      <And>
        <Prefix>key-prefix</Prefix>
        <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
        <ObjectSizeLessThan>64000</ObjectSizeLessThan>
      </And>
    </Filter>
    <Status>Enabled</Status>
    transition/expiration actions
  </Rule>
</LifecycleConfiguration>
```

How Amazon S3 handles conflicts in lifecycle configurations

Generally, Amazon S3 Lifecycle optimizes for cost. For example, if two expiration policies overlap, the shorter expiration policy is honored so that data is not stored for longer than expected. Likewise, if two transition policies overlap, S3 Lifecycle transitions your objects to the lower-cost storage class.

In both cases, S3 Lifecycle tries to choose the path that is least expensive for you. An exception to this general rule is with the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is favored by S3 Lifecycle over any storage class, aside from the S3 Glacier and S3 Glacier Deep Archive storage classes.

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

Examples of overlapping filters and conflicting lifecycle actions

You might specify an S3 Lifecycle configuration in which you specify overlapping prefixes, or actions. The following examples show how Amazon S3 resolves potential conflicts.

Example 1: Overlapping prefixes (no conflict)

The following example configuration has two rules that specify overlapping prefixes as follows:

- The first rule specifies an empty filter, indicating all objects in the bucket.
- The second rule specifies a key name prefix (logs/), indicating only a subset of objects.

Rule 1 requests Amazon S3 to delete all objects one year after creation. Rule 2 requests Amazon S3 to transition a subset of objects to the S3 Standard-IA storage class 30 days after creation.

```
<LifecycleConfiguration>
```

```
<Rule>
  <ID>Rule 1</ID>
  <Filter>
  </Filter>
  <Status>Enabled</Status>
  <Expiration>
    <Days>365</Days>
  </Expiration>
</Rule>
<Rule>
  <ID>Rule 2</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <StorageClass>STANDARD_IA</StorageClass>
    <Days>30</Days>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

Since there is no conflict in this case, Amazon S3 will transition the objects with the logs/ prefix to the S3 Standard-IA storage class 30 days after creation. When any object reaches one year after creation, it will be deleted.

Example 2: Conflicting lifecycle actions

In this example configuration, there are two rules that direct Amazon S3 to perform two different actions on the same set of objects at the same time in the objects' lifetime:

- Both rules specify the same key name prefix, so both rules apply to the same set of objects.
- Both rules specify the same 365 days after object creation when the rules apply.
- One rule directs Amazon S3 to transition objects to the S3 Standard-IA storage class and another rule wants Amazon S3 to expire the objects at the same time.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
```

```
</Filter>
<Status>Enabled</Status>
<Expiration>
  <Days>365</Days>
</Expiration>
</Rule>
<Rule>
  <ID>Rule 2</ID>
  <Filter>
    <Prefix>logs/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <StorageClass>STANDARD_IA</StorageClass>
    <Days>365</Days>
  </Transition>
</Rule>
</LifecycleConfiguration>
```

In this case, because you want objects to expire (to be removed), there is no point in changing the storage class, so Amazon S3 chooses the expiration action on these objects.

Example 3: Overlapping prefixes resulting in conflicting lifecycle actions

In this example, the configuration has two rules, which specify overlapping prefixes as follows:

- Rule 1 specifies an empty prefix (indicating all objects).
- Rule 2 specifies a key name prefix (logs/) that identifies a subset of all objects.

For the subset of objects with the logs/ key name prefix, S3 Lifecycle actions in both rules apply. One rule directs Amazon S3 to transition objects 10 days after creation, and another rule directs Amazon S3 to transition objects 365 days after creation.

```
<LifecycleConfiguration>
<Rule>
  <ID>Rule 1</ID>
  <Filter>
    <Prefix></Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
```

```
<StorageClass>STANDARD_IA</StorageClass>
<Days>10</Days>
</Transition>
</Rule>
<Rule>
<ID>Rule 2</ID>
<Filter>
<Prefix>logs/</Prefix>
</Filter>
<Status>Enabled</Status>
<Transition>
<StorageClass>STANDARD_IA</StorageClass>
<Days>365</Days>
</Transition>
</Rule>
</LifecycleConfiguration>
```

In this case, Amazon S3 chooses to transition them 10 days after creation.

Example 4: Tag-based filtering and resulting conflicting lifecycle actions

Suppose that you have the following S3 Lifecycle configuration that has two rules, each specifying a tag filter:

- Rule 1 specifies a tag-based filter (tag1/value1). This rule directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 365 days after creation.
- Rule 2 specifies a tag-based filter (tag2/value2). This rule directs Amazon S3 to expire objects 14 days after creation.

The S3 Lifecycle configuration is shown in following example.

```
<LifecycleConfiguration>
<Rule>
<ID>Rule 1</ID>
<Filter>
<Tag>
<Key>tag1</Key>
<Value>value1</Value>
</Tag>
</Filter>
<Status>Enabled</Status>
```

```
<Transition>
  <StorageClass>GLACIER</StorageClass>
  <Days>365</Days>
</Transition>
</Rule>
<Rule>
  <ID>Rule 2</ID>
  <Filter>
    <Tag>
      <Key>tag2</Key>
      <Value>value2</Value>
    </Tag>
  </Filter>
  <Status>Enabled</Status>
  <Expiration>
    <Days>14</Days>
  </Expiration>
</Rule>
</LifecycleConfiguration>
```

If an object has both tags, then Amazon S3 has to decide which rule to follow. In this case, Amazon S3 expires the object 14 days after creation. The object is removed, and therefore the transition action does not apply.

Examples of S3 Lifecycle configurations

This section provides examples of S3 Lifecycle configuration. Each example shows how you can specify the XML in each of the example scenarios.

Topics

- [Archiving all objects within one day after creation](#)
- [Disabling Lifecycle rules temporarily](#)
- [Tiering down the storage class over an object's lifetime](#)
- [Specifying multiple rules](#)
- [Specifying a lifecycle rule for a versioning-enabled bucket](#)
- [Removing expired object delete markers in a versioning-enabled bucket](#)
- [Lifecycle configuration to abort multipart uploads](#)

- [Expiring noncurrent objects that have no data](#)
- [Example: Allowing objects smaller than 128 KB to be transitioned](#)

Archiving all objects within one day after creation

Each S3 Lifecycle rule includes a filter that you can use to identify a subset of objects in your bucket to which the S3 Lifecycle rule applies. The following S3 Lifecycle configurations show examples of how you can specify a filter.

- In this S3 Lifecycle configuration rule, the filter specifies a key prefix (tax/). Therefore, the rule applies to objects with the key name prefix tax/, such as tax/doc1.txt and tax/doc2.txt.

The rule specifies two actions that direct Amazon S3 to do the following:

- Transition objects to the S3 Glacier Flexible Retrieval storage class 365 days (one year) after creation.
- Delete objects (the Expiration action) 3,650 days (10 years) after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition and Expiration Rule</ID>
    <Filter>
      <Prefix>tax/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>3650</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

Instead of specifying the object age in terms of days after creation, you can specify a date for each action. However, you can't use both Date and Days in the same rule.

- If you want the S3 Lifecycle rule to apply to all objects in the bucket, specify an empty prefix. In the following configuration, the rule specifies a Transition action that directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 0 days after creation. This

rule means that the objects are eligible for archival to S3 Glacier Flexible Retrieval at midnight UTC following creation. For more information about lifecycle constraints, see [Constraints and considerations for transitions](#).

```
<LifecycleConfiguration>
  <Rule>
    <ID>Archive all object same-day upon creation</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

- You can specify zero or one key name prefix and zero or more object tags in a filter. The following example code applies the S3 Lifecycle rule to a subset of objects with the tax/ key prefix and to objects that have two tags with specific key and value. When you specify more than one filter, you must include the `<And>` element as shown (Amazon S3 applies a logical AND to combine the specified filter conditions).

```
...
<Filter>
  <And>
    <Prefix>tax/</Prefix>
    <Tag>
      <Key>key1</Key>
      <Value>value1</Value>
    </Tag>
    <Tag>
      <Key>key2</Key>
      <Value>value2</Value>
    </Tag>
  </And>
</Filter>
...
```

- You can filter objects based only on tags. For example, the following S3 Lifecycle rule applies to objects that have the two specified tags (it does not specify any prefix).

```
...  
<Filter>  
  <And>  
    <Tag>  
      <Key>key1</Key>  
      <Value>value1</Value>  
    </Tag>  
    <Tag>  
      <Key>key2</Key>  
      <Value>value2</Value>  
    </Tag>  
  </And>  
</Filter>  
...
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Disabling Lifecycle rules temporarily

You can temporarily disable an S3 Lifecycle rule using the `status` element. This can be useful if you want to test new rules or troubleshoot issues with your configuration, without overwriting your existing rules. The following S3 Lifecycle configuration specifies two rules:

- Rule 1 directs Amazon S3 to transition objects with the `logs/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.
- Rule 2 directs Amazon S3 to transition objects with the `documents/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.

In the configuration, Rule 1 is enabled and Rule 2 is disabled. Amazon S3 ignores the disabled rule.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule2</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Disabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Tiering down the storage class over an object's lifetime

In this example, you use S3 Lifecycle configuration to tier down the storage class of objects over their lifetime. Tiering down can help reduce storage costs. For more information about pricing, see [Amazon S3 pricing](#).

The following S3 Lifecycle configuration specifies a rule that applies to objects with the key name prefix logs/. The rule specifies the following actions:

- Two transition actions:
 - Transition objects to the S3 Standard-IA storage class 30 days after creation.
 - Transition objects to the S3 Glacier Flexible Retrieval storage class 90 days after creation.
- One expiration action that directs Amazon S3 to delete objects a year after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>example-id</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>30</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <Transition>
      <Days>90</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

Note

You can use one rule to describe all S3 Lifecycle actions if all actions apply to the same set of objects (identified by the filter). Otherwise, you can add multiple rules with each specifying a different filter.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Specifying multiple rules

You can specify multiple rules if you want different S3 Lifecycle actions of different objects. The following S3 Lifecycle configuration has two rules:

- Rule 1 applies to objects with the key name prefix `classA/`. It directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class one year after creation and expire these objects 10 years after creation.
- Rule 2 applies to objects with key name prefix `classB/`. It directs Amazon S3 to transition objects to the S3 Standard-IA storage class 90 days after creation and delete them one year after creation.

```
<LifecycleConfiguration>
```

```
<Rule>
  <ID>ClassADocRule</ID>
  <Filter>
    <Prefix>classA/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>365</Days>
    <StorageClass>GLACIER</StorageClass>
  </Transition>
  <Expiration>
    <Days>3650</Days>
  </Expiration>
</Rule>
<Rule>
  <ID>ClassBDocRule</ID>
  <Filter>
    <Prefix>classB/</Prefix>
  </Filter>
  <Status>Enabled</Status>
  <Transition>
    <Days>90</Days>
    <StorageClass>STANDARD_IA</StorageClass>
  </Transition>
  <Expiration>
    <Days>365</Days>
  </Expiration>
</Rule>
</LifecycleConfiguration>
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of [delete markers](#).
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see [Examples of overlapping filters and conflicting lifecycle actions](#).

Specifying a lifecycle rule for a versioning-enabled bucket

Suppose that you have a versioning-enabled bucket, which means that for each object, you have a current version and zero or more noncurrent versions. (For more information about S3 Versioning, see [Retaining multiple versions of objects with S3 Versioning](#).)

In the following example, you want to maintain one year's worth of history, and retain 5 noncurrent versions. S3 Lifecycle configurations support keeping 1 to 100 versions of any object. Be aware that more than 5 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the NoncurrentDays and the NewerNoncurrentVersions values must be exceeded.

To save storage costs, you want to move noncurrent versions to S3 Glacier Flexible Retrieval 30 days after they become noncurrent (assuming that these noncurrent objects are cold data for which you don't need real-time access). In addition, you expect the frequency of access of the current versions to diminish 90 days after creation, so you might choose to move these objects to the S3 Standard-IA storage class.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>90</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <NoncurrentVersionTransition>
      <NoncurrentDays>30</NoncurrentDays>
      <StorageClass>GLACIER</StorageClass>
    </NoncurrentVersionTransition>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>5</NewerNoncurrentVersions>
```

```
<NoncurrentDays>365</NoncurrentDays>
</NoncurrentVersionExpiration>
</Rule>
</LifecycleConfiguration>
```

Removing expired object delete markers in a versioning-enabled bucket

A versioning-enabled bucket has one current version and zero or more noncurrent versions for each object. When you delete an object, note the following:

- If you don't specify a version ID in your delete request, Amazon S3 adds a delete marker instead of deleting the object. The current object version becomes noncurrent, and the delete marker becomes the current version.
- If you specify a version ID in your delete request, Amazon S3 deletes the object version permanently (a delete marker isn't created).
- A delete marker with zero noncurrent versions is referred to as an *expired object delete marker*.

This example shows a scenario that can create expired object delete markers in your bucket, and how you can use S3 Lifecycle configuration to direct Amazon S3 to remove the expired object delete markers.

Suppose that you write an S3 Lifecycle configuration that uses the NoncurrentVersionExpiration action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions, as shown in the following example. Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the NoncurrentDays and the NewerNoncurrentVersions values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

The NoncurrentVersionExpiration action doesn't apply to the current object versions. It removes only the noncurrent versions.

For current object versions, you have the following options to manage their lifetime, depending on whether the current object versions follow a well-defined lifecycle:

- **The current object versions follow a well-defined lifecycle.**

In this case, you can use an S3 Lifecycle configuration with the Expiration action to direct Amazon S3 to remove the current versions, as shown in the following example.

```
<LifecycleConfiguration>
  <Rule>
    ...
    <Expiration>
      <Days>60</Days>
    </Expiration>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

In this example, Amazon S3 removes current versions 60 days after they're created by adding a delete marker for each of the current object versions. This process makes the current version noncurrent, and the delete marker becomes the current version. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

 **Note**

You can't specify both a Days and an ExpiredObjectDeleteMarker tag on the same rule. When you specify the Days tag, Amazon S3 automatically performs ExpiredObjectDeleteMarker cleanup when the delete markers are old enough to satisfy the age criteria. To clean up delete markers as soon as they become the only version, create a separate rule with only the ExpiredObjectDeleteMarker tag.

The NoncurrentVersionExpiration action in the same S3 Lifecycle configuration removes noncurrent objects 30 days after they become noncurrent. Thus, in this example, all object

versions are permanently removed 90 days after object creation. Be aware that in this example, more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the NoncurrentDays and the NewerNoncurrentVersions values must be exceeded.

Although expired object delete markers are created during this process, Amazon S3 detects and removes the expired object delete markers for you.

- **The current object versions don't have a well-defined lifecycle.**

In this case, you might remove the objects manually when you don't need them, creating a delete marker with one or more noncurrent versions. If your S3 Lifecycle configuration with the NoncurrentVersionExpiration action removes all the noncurrent versions, you now have expired object delete markers.

Specifically for this scenario, S3 Lifecycle configuration provides an **Expiration** action that you can use to remove the expired object delete markers.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule_1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <ExpiredObjectDeleteMarker>true</ExpiredObjectDeleteMarker>
    </Expiration>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

By setting the **ExpiredObjectDeleteMarker** element to **true** in the **Expiration** action, you direct Amazon S3 to remove the expired object delete markers.

Note

When you use the `ExpiredObjectDeleteMarker` S3 Lifecycle action, the rule cannot specify a tag-based filter.

Lifecycle configuration to abort multipart uploads

You can use the Amazon S3 multipart upload REST API operations to upload large objects in parts. For more information about multipart uploads, see [Uploading and copying objects using multipart upload in Amazon S3](#).

By using an S3 Lifecycle configuration, you can direct Amazon S3 to stop incomplete multipart uploads (identified by the key name prefix specified in the rule) if they aren't completed within a specified number of days after initiation. When Amazon S3 aborts a multipart upload, it deletes all the parts associated with the multipart upload. This process helps control your storage costs by ensuring that you don't have incomplete multipart uploads with parts that are stored in Amazon S3.

Note

When you use the `AbortIncompleteMultipartUpload` S3 Lifecycle action, the rule cannot specify a tag-based filter.

The following is an example S3 Lifecycle configuration that specifies a rule with the `AbortIncompleteMultipartUpload` action. This action directs Amazon S3 to stop incomplete multipart uploads seven days after initiation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>sample-rule</ID>
    <Filter>
      <Prefix>SomeKeyPrefix</Prefix>
    </Filter>
    <Status>rule-status</Status>
    <AbortIncompleteMultipartUpload>
      <DaysAfterInitiation>7</DaysAfterInitiation>
    </AbortIncompleteMultipartUpload>
  </Rule>
```

```
</LifecycleConfiguration>
```

Expiring noncurrent objects that have no data

You can create rules that transition objects based only on their size. You can specify a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes in bytes. When using more than one filter, such as a prefix and size rule, you must wrap the filters in an `<And>` element.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition with a prefix and based on size</ID>
    <Filter>
      <And>
        <Prefix>tax/</Prefix>
        <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
      </And>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

If you're specifying a range by using both the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` elements, the maximum object size must be larger than the minimum object size. When using more than one filter, you must wrap the filters in an `<And>` element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes. When you're specifying a range, the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For more information, see [the section called "Filter element"](#).

```
<LifecycleConfiguration>
  <Rule>
    ...
    <And>
      <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
      <ObjectSizeLessThan>64000</ObjectSizeLessThan>
    </And>
  </Rule>
```

```
</LifecycleConfiguration>
```

You can also create rules to specifically expire noncurrent objects that have no data, including noncurrent delete marker objects created in a versioning-enabled bucket. The following example uses the NoncurrentVersionExpiration action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions. This example also uses the ObjectSizeLessThan element to filter only objects with no data.

Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the NoncurrentDays and the NewerNoncurrentVersions values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Expire noncurrent with size less than 1 byte</ID>
    <Filter>
      <ObjectSizeLessThan>1</ObjectSizeLessThan>
    </Filter>
    <Status>Enabled</Status>
    <NoncurrentVersionExpiration>
      <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
      <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
</LifecycleConfiguration>
```

Example: Allowing objects smaller than 128 KB to be transitioned

Amazon S3 applies a default behavior to your Lifecycle configuration that prevents objects smaller than 128 KB from being transitioned to any storage class. You can allow smaller objects to transition by adding a minimum size (ObjectSizeGreaterThanOrEqual) or a maximum size (ObjectSizeLessThan) filter that specifies a smaller size to the configuration. The following example allows any object smaller than 128 KB to transition to the S3 Glacier Instant Retrieval storage class:

```
<LifecycleConfiguration>
  <Rule>
    <ID>Allow small object transitions</ID>
    <Filter>
      <ObjectSizeGreaterThanOrEqual>1</ObjectSizeGreaterThanOrEqual>
```

```
</Filter>
<Status>Enabled</Status>
<Transition>
  <Days>365</Days>
  <StorageClass>GLACIER_IR</StorageClass>
</Transition>
</Rule>
</LifecycleConfiguration>
```

Note

In September 2024, Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case requires, you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-object-size-minimum-default` header in a [PutBucketLifecycleConfiguration](#) request.

The following example shows how to use the `x-amz-transition-object-size-minimum-default` header in a [PutBucketLifecycleConfiguration](#) request to apply the `varies_by_storage_class` default transition behavior to an S3 Lifecycle configuration. This behavior allows object smaller than 128 KB to transition to the S3 Glacier or S3 Glacier Deep Archive storage classes. By default, all other storage classes will prevent transitions smaller than 128 KB. You can still use custom filters to change the minimum transition size for any storage class. Custom filters always take precedence over the default transition behavior:

```
HTTP/1.1 200
```

```
x-amz-transition-object-size-minimum-default: varies_by_storage_class
<?xml version="1.0" encoding="UTF-8"?>
...

```

Troubleshooting Amazon S3 Lifecycle issues

The following information can help you troubleshoot common issues with Amazon S3 Lifecycle rules.

Topics

- [I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.](#)
- [How do I monitor the actions taken by my lifecycle rules?](#)
- [My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.](#)
- [How do I empty my S3 bucket by using lifecycle rules?](#)
- [My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.](#)
- [I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.](#)
- [Can I recover S3 objects that are expired by S3 Lifecycle rules?](#)
- [How can I exclude a prefix from my lifecycle rule?](#)
- [How can I include multiple prefixes in my lifecycle rule?](#)

I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.

S3 Lifecycle [object transitions](#) and [object expirations](#) are asynchronous operations. Therefore, there might be a delay between the time that the objects are eligible for expiration or transition and the time that they are actually transitioned or expired. Changes in billing are applied as soon as the lifecycle rule is satisfied, even if the action isn't complete. The exception to this behavior is if you have a lifecycle rule set to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about changes in billing, see [Setting lifecycle configuration on a bucket](#).

Note

Amazon S3 doesn't transition objects that are smaller than 128 KB from the S3 Standard or S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage class.

How do I monitor the actions taken by my lifecycle rules?

To monitor actions taken by lifecycle rules, you can use the following features:

- **S3 Event Notifications** – You can set up [S3 Event Notifications](#) so that you're notified of any S3 Lifecycle expiration or transition events.
- **S3 server access logs** – You can enable server access logs for your S3 buckets to capture S3 Lifecycle actions, such as object transitions to another storage class or object expirations. For more information, see [Lifecycle and logging](#).

To view the changes in your storage caused by lifecycle actions on a daily basis, we recommend using [S3 Storage Lens dashboards](#) instead of using Amazon CloudWatch metrics. In your Storage Lens dashboard, you can view the following metrics, which monitor the object count or size:

- **Current version bytes**
- **Current version object count**
- **Noncurrent version bytes**
- **Noncurrent version object count**
- **Delete marker object count**
- **Delete marker storage bytes**
- **Incomplete multipart upload bytes**
- **Incomplete multipart upload object count**

My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.

In a [versioning-enabled bucket](#), when an object is expired, the object isn't completely deleted from the bucket. Instead, a [delete marker](#) is created as the newest version of the object. Delete

markers are still counted as objects. Therefore, if a lifecycle rule is created to expire only the current versions, then the object count in the S3 bucket actually increases instead of going down.

For example, let's say an S3 bucket is versioning-enabled with 100 objects, and a lifecycle rule is set to expire current versions of the object after 7 days. After the seventh day, the object count increases to 200 because 100 delete markers are created in addition to the 100 original objects, which are now the noncurrent versions. For more information about S3 Lifecycle configuration rule actions for versioning-enabled buckets, see [Setting lifecycle configuration on a bucket](#).

To permanently remove objects, add an additional lifecycle configuration to delete the previous versions of the objects, expired delete markers, and incomplete multipart uploads. For instructions on how to create new lifecycle rules, see [Setting lifecycle configuration on a bucket](#).

 **Note**

- Amazon S3 rounds the transition or expiration date of an object to midnight UTC the next day.

When evaluating objects for lifecycle actions, Amazon S3 uses the object creation time in UTC. For example, consider a nonversioned bucket with a lifecycle rule that's configured to expire objects after one day. Suppose that an object was created on January 1 at 17:05 Pacific Daylight Time (PDT), which corresponds to January 2 at 00:05 UTC. The object becomes one day old at 00:05 UTC on January 3, which makes it eligible for expiration when S3 Lifecycle evaluates objects at 00:00 UTC on January 4.

Because Amazon S3 lifecycle actions occur asynchronously, there might be some delay between the date specified in the lifecycle rule and the actual physical transition of the object. For more information, see [Transition or expiration delay](#).

For more information, see [Lifecycle rules: Based on an object's age](#).

- For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

How do I empty my S3 bucket by using lifecycle rules?

S3 Lifecycle rules are an effective tool to [empty an S3 bucket](#) with millions of objects. To delete a large number of objects from your S3 bucket, make sure to use these two pairs of lifecycle rules:

- **Expire current versions of objects and Permanently delete previous versions of objects**
- **Delete expired delete markers and Delete incomplete multipart uploads**

For steps on how to create a lifecycle configuration rule, see [Setting lifecycle configuration on a bucket](#).

 **Note**

For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.

There are several reasons that your bill might increase after transitioning objects to a lower-cost storage class:

- S3 Glacier overhead charges for small objects

For each object that is transitioned to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a total overhead of 40 KB is associated with this storage update. As part of the 40 KB overhead, 8 KB is used to store metadata and the name of the object. This 8 KB is charged according to S3 Standard rates. The remaining 32 KB is used for indexing and related metadata. This 32 KB is charged according to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive pricing.

Therefore, if you're storing many smaller sized objects, we don't recommend using lifecycle transitions. Instead, to reduce any overhead charges, consider aggregating many smaller objects into a smaller number of large objects before storing them in Amazon S3. For more information about cost considerations, see [Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes \(object archival\)](#).

- Minimum storage charges

Some S3 storage classes have minimum storage-duration requirements. Objects that are deleted, overwritten, or transitioned from those classes before the minimum duration is satisfied are charged a prorated early transition or deletion fee. These minimum storage-duration requirements are as follows:

- S3 Standard-IA and S3 One Zone-IA – 30 days
- S3 Glacier Flexible Retrieval and S3 Glacier Instant Retrieval – 90 days
- S3 Glacier Deep Archive – 180 days

For more information about these requirements, see the *Constraints* section of [Transitioning objects using S3 Lifecycle](#). For general S3 pricing information, see [Amazon S3 pricing](#) and the [AWS Pricing Calculator](#).

- Lifecycle transition costs

Each time an object is transitioned to a different storage class by a lifecycle rule, Amazon S3 counts that transition as one transition request. The costs for these transition requests are in addition to the costs of these storage classes. If you plan to transition a large number of objects, consider the request costs when transitioning to a lower tier. For more information, see [Amazon S3 pricing](#).

I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.

Deny statements in a bucket policy don't prevent the expiration of the objects defined in a lifecycle rule. Lifecycle actions (such as transitions or expirations) don't use the S3 DeleteObject operation. Instead, S3 Lifecycle actions are performed by using internal S3 endpoints. (For more information, see [Lifecycle and logging](#).)

To prevent your lifecycle rule from taking any action, you must edit, delete, or [disable the rule](#).

Can I recover S3 objects that are expired by S3 Lifecycle rules?

The only way to recover objects that are expired by S3 Lifecycle is through versioning, which must be in place before the objects become eligible for expiration. You cannot undo the expiration operations that are performed by lifecycle rules. If objects are permanently deleted by the S3 Lifecycle rules that are in place, you cannot recover these objects. To enable versioning on a bucket, see [the section called "Retaining multiple versions of objects"](#).

If you have applied versioning to the bucket and the noncurrent versions of the objects are still intact, you can [restore previous versions of the expired objects](#). For more information about the behavior of S3 Lifecycle rule actions and versioning states, see the *Lifecycle actions and bucket versioning state* table in [Elements to describe lifecycle actions](#).

Note

If the S3 bucket is protected by [AWS Backup](#) or [S3 Replication](#), you might also be able to use these features to recover your expired objects.

How can I exclude a prefix from my lifecycle rule?

S3 Lifecycle doesn't support excluding prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see [the section called "Archiving all objects within one day after creation"](#).

How can I include multiple prefixes in my lifecycle rule?

S3 Lifecycle doesn't support including multiple prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see [the section called "Archiving all objects within one day after creation"](#).

However, if you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/  
sales2000/  
sales2001/
```

To include all three prefixes in your rule, specify <Prefix>sales</Prefix> in your lifecycle rule.

Logging and monitoring in Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. We recommend collecting monitoring data from all of the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs. Before you start monitoring Amazon S3, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

For more information about logging and monitoring in Amazon S3, see the following topics.

Note

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon S3 resources and responding to potential incidents.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Amazon GuardDuty

[Amazon GuardDuty](#) is a threat detection service that continuously monitors your accounts, containers, workloads, and the data within your AWS environment to identify potential threats or security risks to your S3 buckets. GuardDuty also provides rich context about the threats that it detects. GuardDuty monitors AWS CloudTrail management logs for threats and surfaces security relevant information. For example, GuardDuty will include factors of an API request, such as the user that made the request, the location the request was made from, and the specific API requested, that could be unusual in your environment. [GuardDuty S3 Protection](#) monitors the S3 data events collected by CloudTrail and identifies potentially anomalous and malicious behavior in all the S3 buckets in your environment.

Amazon S3 Access Logs

Server access logs provide detailed records about requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. For more information, see [Logging requests with server access logging](#).

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon S3-related checks:

- Logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that don't have versioning enabled, or have versioning suspended.

For more information, see [AWS Trusted Advisor](#) in the *Support User Guide*.

Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads.

S3 Storage Lens aggregates your metrics and displays the information in the Account snapshot section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. For more information, see [Understanding Amazon S3 Storage Lens](#).

Amazon S3 Inventory

Amazon S3 Inventory generates a list of objects and metadata that you can use to query and manage your objects. You can use this inventory report to generate granular data such as object size, last modified date, encryption status and other fields. Those reports are available daily or weekly to automatically give the latest list.

For example, you can use Amazon S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also use Amazon S3 Inventory to simplify and speed up business workflows and big data jobs, which provides a scheduled alternative to the Amazon S3 synchronous List API operations. Amazon S3 Inventory doesn't use the List API operations to audit your objects and does not affect the request rate of your bucket. For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

Amazon S3 Event Notifications

With the Amazon S3 Event Notifications feature, you receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that identifies the events that you want Amazon S3 to publish. For more information, see [Amazon S3 Event Notifications](#).

Amazon S3 and AWS X-Ray

AWS X-Ray integrates with Amazon S3 to trace upstream requests to update your application's S3 buckets. If a service traces requests by using the X-Ray SDK, Amazon S3 can send the tracing headers to downstream event subscribers such as Lambda, Amazon SQS, and Amazon SNS. X-Ray enables trace messages for Amazon S3 event notifications. You can use the X-Ray trace map to view the connections between Amazon S3 and other services that your application uses. For more information, see [Amazon S3 and X-Ray](#).

The following security best practices also address logging and monitoring:

- [Identify and audit all your Amazon S3 buckets](#)
- [Implement monitoring using Amazon Web Services monitoring tools](#)
- [Enable AWS Config](#)
- [Enable Amazon S3 server access logging](#)
- [Use CloudTrail](#)
- [Monitor Amazon Web Services security advisories](#)

Topics

- [Monitoring tools](#)
- [Logging options for Amazon S3](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Logging requests with server access logging](#)
- [Monitoring metrics with Amazon CloudWatch](#)
- [Amazon S3 Event Notifications](#)
- [Assessing your storage activity and usage with Amazon S3 Storage Lens](#)
- [Cataloging and analyzing your data with S3 Inventory](#)

Monitoring tools

AWS provides various tools that you can use to monitor Amazon S3. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon S3 and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring metrics with Amazon CloudWatch](#).
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

Manual monitoring tools

Another important part of monitoring Amazon S3 involves manually monitoring those items that the CloudWatch alarms don't cover. The Amazon S3, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. You might want to enable *server access logging*, which tracks requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. For more information, see [Logging requests with server access logging](#).

- The Amazon S3 dashboard shows the following:
 - Your buckets and the objects and properties they contain
- The CloudWatch home page shows the following:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about.

- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.
- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

Trusted Advisor has these checks that relate to Amazon S3:

- Checks of the logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that do not have versioning enabled, or have versioning suspended.

Logging options for Amazon S3

You can record the actions that are taken by users, roles, or AWS services on Amazon S3 resources and maintain log records for auditing and compliance purposes. To do this, you can use server-access logging, AWS CloudTrail logging, or a combination of both. We recommend that you use CloudTrail for logging bucket-level and object-level actions for your Amazon S3 resources. For more information about each option, see the following sections:

- [Logging requests with server access logging](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)

The following table lists the key properties of CloudTrail logs and Amazon S3 server-access logs. To make sure that CloudTrail meets your security requirements, review the table and notes.

Log properties	AWS CloudTrail	Amazon S3 server logs
Can be forwarded to other systems (Amazon CloudWatch Logs, Amazon CloudWatch Events)	Yes	No

Log properties	AWS CloudTrail	Amazon S3 server logs
Deliver logs to more than one destination (for example, send the same logs to two different buckets)	Yes	No
Turn on logs for a subset of objects (prefix)	Yes	No
Cross-account log delivery (target and source bucket owned by different accounts)	Yes	No
Integrity validation of log file by using digital signature or hashing	Yes	No
Default or choice of encryption for log files	Yes	No
Object operations (by using Amazon S3 APIs)	Yes	Yes
Bucket operations (by using Amazon S3 APIs)	Yes	Yes
Searchable UI for logs	Yes	No
Fields for Object Lock parameters, Amazon S3 Select properties for log records	Yes	No
Fields for Object Size, Total Time, Turn-Around Time, and HTTP Referer for log records	No	Yes

Log properties	AWS CloudTrail	Amazon S3 server logs
Lifecycle transitions, expiration, restores	No	Yes
Logging of keys in a batch delete operation	No	Yes
Authentication failures ¹	No	Yes
Accounts where logs get delivered	Bucket owner ² , and requester	Bucket owner only
Performance and Cost	AWS CloudTrail	Amazon S3 Server Logs
Price	Management events (first delivery) are free; data events incur a fee, in addition to storage of logs	No other cost in addition to storage of logs
Speed of log delivery	Data events every 5 minutes; management events every 15 minutes	Within a few hours
Log format	JSON	Log file with space-separated, newline-delimited records

Notes

- CloudTrail does not deliver logs for requests that fail authentication (in which the provided credentials are not valid). However, it does include logs for requests in which authorization fails (AccessDenied) and requests that are made by anonymous users.
- The S3 bucket owner receives CloudTrail logs when the account does not have full access to the object in the request. For more information, see [Amazon S3 object-level actions in cross-account scenarios](#).
- S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Logging Amazon S3 API calls using AWS CloudTrail

Amazon S3 is integrated with [AWS CloudTrail](#), a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. The calls captured include calls from the Amazon S3 console and code calls to the Amazon S3 API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see [Working with CloudTrail Event history](#) in the [AWS CloudTrail User Guide](#). There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a [CloudTrail Lake](#) event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see [Creating a trail for your AWS account](#) and [Creating a trail for an organization](#) in the [AWS CloudTrail User Guide](#).

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For

more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#). For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to [Apache ORC](#) format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying [advanced event selectors](#). The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see [Working with AWS CloudTrail Lake](#) in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the [pricing option](#) you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can store your log files in your bucket for as long as you want, but you can also define Amazon S3 Lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted by using Amazon S3 server-side encryption (SSE).

Using CloudTrail logs with Amazon S3 server access logs and CloudWatch Logs

AWS CloudTrail logs provide a record of actions taken by a user, role, or an AWS service in Amazon S3, while Amazon S3 server access logs provide detailed records for the requests that are made to an S3 bucket. For more information about how the different logs work, and their properties, performance, and costs, see [the section called “Logging options”](#).

You can use AWS CloudTrail logs together with server access logs for Amazon S3. CloudTrail logs provide you with detailed API tracking for Amazon S3 bucket-level and object-level operations. Server access logs for Amazon S3 provide you with visibility into object-level operations on your data in Amazon S3. For more information about server access logs, see [Logging requests with server access logging](#).

You can also use CloudTrail logs together with Amazon CloudWatch for Amazon S3. CloudTrail integration with CloudWatch Logs delivers S3 bucket-level API activity captured by CloudTrail to a

CloudWatch log stream in the CloudWatch log group that you specify. You can create CloudWatch alarms for monitoring specific API activity and receive email notifications when the specific API activity occurs. For more information about CloudWatch alarms for monitoring specific API activity, see the [AWS CloudTrail User Guide](#). For more information about using CloudWatch with Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

 **Note**

S3 does not support delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

CloudTrail tracking with Amazon S3 SOAP API calls

CloudTrail tracks Amazon S3 SOAP API calls. Amazon S3 SOAP support over HTTP is deprecated, but it is still available over HTTPS. For more information about Amazon S3 SOAP support, see [Appendix: SOAP API](#) in the *Amazon S3 API Reference*.

 **Important**

Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

The following table shows Amazon S3 SOAP actions tracked by CloudTrail logging.

SOAP API name	API event name used in CloudTrail log
ListAllMyBuckets	ListBuckets
CreateBucket	CreateBucket
DeleteBucket	DeleteBucket
GetBucketAccessControlPolicy	GetBucketAcl
SetBucketAccessControlPolicy	PutBucketAcl
GetBucketLoggingStatus	GetBucketLogging

SOAP API name	API event name used in CloudTrail log
SetBucketLoggingStatus	PutBucketLogging

For more information about CloudTrail and Amazon S3, see the following topics:

Topics

- [Amazon S3 CloudTrail events](#)
- [CloudTrail log file entries for Amazon S3 and S3 on Outposts](#)
- [Enabling CloudTrail event logging for S3 buckets and objects](#)
- [Identifying Amazon S3 requests using CloudTrail](#)

Amazon S3 CloudTrail events

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

This section provides information about the events that S3 logs to CloudTrail.

Amazon S3 data events in CloudTrail

[Data events](#) provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can log data events for the Amazon S3 resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see [Logging data events with the AWS Management Console](#) and [Logging data events with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

The following table lists the Amazon S3 resource types for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3	AWS::S3::Object	<ul style="list-style-type: none">• AbortMultipartUpload• CompleteMultipartUpload• CopyObject• CreateMultipartUpload• DeleteObject• DeleteObjectTagging• DeleteObjects• GetObject• GetObjectAcl• GetObjectAttributes• GetObjectLegalHold• GetObjectRetention• GetObjectTagging• GetObjectTorrent• HeadObject• ListMultipartUploads

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resources.ARN` fields to log only those events that are important to you. For more information about these fields, see [AdvancedFieldSelector](#) in the *AWS CloudTrail API Reference*.

Amazon S3 management events in CloudTrail

Amazon S3 logs all control plane operations as management events. For more information about S3 API operations, see the [Amazon S3 API Reference](#).

How CloudTrail captures requests made to Amazon S3

By default, CloudTrail logs S3 bucket-level API calls that were made in the last 90 days, but not log requests made to objects. Bucket-level calls include events such as `CreateBucket`, `DeleteBucket`, `PutBucketLifecycle`, `PutBucketPolicy`, and so on. You can see bucket-level events on the CloudTrail console. However, you can't view data events (Amazon S3 object-level calls) there—you must parse or query CloudTrail logs for them.

Amazon S3 account-level actions tracked by CloudTrail logging

CloudTrail logs account-level actions. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

The tables in this section list the Amazon S3 account-level actions that are supported for logging by CloudTrail.

Amazon S3 account-level API actions tracked by CloudTrail logging appear as the following event names. The CloudTrail event names differ from the API action name. For example, `DeletePublicAccessBlock` is `DeleteAccountPublicAccessBlock`.

- [DeleteAccountPublicAccessBlock](#)
- [GetAccountPublicAccessBlock](#)
- [PutAccountPublicAccessBlock](#)

Amazon S3 bucket-level actions that are tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for general purpose buckets. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

This section lists the Amazon S3 bucket-level actions that are supported for logging by CloudTrail.

Amazon S3 bucket-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name. For example, `PutBucketLifecycleConfiguration` is `PutBucketLifecycle`.

- [CreateBucket](#)
- [CreateBucketMetadataTableConfiguration](#)

- [DeleteBucket](#)
- [DeleteBucketAnalyticsConfiguration](#)
- [DeleteBucketCors](#)
- [DeleteBucketEncryption](#)
- [DeleteBucketIntelligentTieringConfiguration](#)
- [DeleteBucketInventoryConfiguration](#)
- [DeleteBucketLifecycle](#)
- [DeleteBucketMetadataTableConfiguration](#)
- [DeleteBucketMetricsConfiguration](#)
- [DeleteBucketOwnershipControls](#)
- [DeleteBucketPolicy](#)
- [DeleteBucketPublicAccessBlock](#)
- [DeleteBucketReplication](#)
- [DeleteBucketTagging](#)
- [GetAccelerateConfiguration](#)
- [GetBucketAcl](#)
- [GetBucketAnalyticsConfiguration](#)
- [GetBucketCors](#)
- [GetBucketEncryption](#)
- [GetBucketIntelligentTieringConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [GetBucketLifecycle](#)
- [GetBucketLocation](#)
- [GetBucketLogging](#)
- [GetBucketMetadataTableConfiguration](#)
- [GetBucketMetricsConfiguration](#)
- [GetBucketNotification](#)
- [GetBucketObjectLockConfiguration](#)
- [GetBucketOwnershipControls](#)

- [GetBucketPolicy](#)
- [GetBucketPolicyStatus](#)
- [GetBucketPublicAccessBlock](#)
- [GetBucketReplication](#)
- [GetBucketRequestPayment](#)
- [GetBucketTagging](#)
- [GetBucketVersioning](#)
- [GetBucketWebsite](#)
- [HeadBucket](#)
- [ListBuckets](#)
- [PutAccelerateConfiguration](#)
- [PutBucketAcl](#)
- [PutBucketAnalyticsConfiguration](#)
- [PutBucketCors](#)
- [PutBucketEncryption](#)
- [PutBucketIntelligentTieringConfiguration](#)
- [PutBucketInventoryConfiguration](#)
- [PutBucketLifecycle](#)
- [PutBucketLogging](#)
- [PutBucketMetricsConfiguration](#)
- [PutBucketNotification](#)
- [PutBucketObjectLockConfiguration](#)
- [PutBucketOwnershipControls](#)
- [PutBucketPolicy](#)
- [PutBucketPublicAccessBlock](#)
- [PutBucketReplication](#)
- [PutBucketRequestPayment](#)
- [PutBucketTagging](#)
- [PutBucketVersioning](#)
- [PutBucketWebsite](#)

In addition to these API operations, you can also use the [OPTIONS object](#) object-level action. This action is treated like a bucket-level action in CloudTrail logging because the action checks the CORS configuration of a bucket.

Amazon S3 Express One Zone bucket-level (Regional API endpoint) actions tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The eventsource for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`.

These following Regional endpoint API operations are logged to CloudTrail.

- [CreateBucket](#)
- [DeleteBucket](#)
- [DeleteBucketPolicy](#)
- [GetBucketPolicy](#)
- [PutBucketPolicy](#)
- [ListDirectoryBuckets](#)
- [PutBucketEncryption](#)
- [GetBucketEncryption](#)
- [DeleteBucketEncryption](#)

For more information, see [Logging with AWS CloudTrail for S3 Express One Zone](#)

Amazon S3 object-level actions in cross-account scenarios

The following are special use cases involving the object-level API calls in cross-account scenarios and how CloudTrail logs are reported. CloudTrail delivers logs to the requester (the account that made the API call), except in some access denied cases where log entries are redacted or omitted. When setting up cross-account access, consider the examples in this section.

 **Note**

The examples assume that CloudTrail logs are appropriately configured.

Example 1: CloudTrail delivers logs to the bucket owner

CloudTrail delivers logs to the bucket owner even if the bucket owner does not have permissions for the same object API operation. Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) tries to access an object in that bucket.
- Account C owns the object. Account C might or might not be the same account as Account A.

Note

CloudTrail always delivers object-level API logs to the requester (Account B). In addition, CloudTrail also delivers the same logs to the bucket owner (Account A) even when the bucket owner does not own the object (Account C) or have permissions for those same API operations on that object.

Example 2: CloudTrail does not proliferate email addresses that are used in setting object ACLs

Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) sends a request to set an object ACL grant by using an email address. For more information about ACLs, see [Access control list \(ACL\) overview](#).

The requester gets the logs along with the email information. However, the bucket owner—if they are eligible to receive logs, as in example 1—gets the CloudTrail log reporting the event. However, the bucket owner doesn't get the ACL configuration information, specifically the grantee email address and the grant. The only information that the log tells the bucket owner is that an ACL API call was made by Account B.

CloudTrail log file entries for Amazon S3 and S3 on Outposts

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and

with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

Note

To view CloudTrail log file examples for Amazon S3 Express One Zone, see [CloudTrail log file examples for S3 Express One Zone](#).

For more information, see the following examples.

Topics

- [Example: CloudTrail log file entry for Amazon S3](#)

Example: CloudTrail log file entry for Amazon S3

The following example shows a CloudTrail log entry that demonstrates the [GET Service](#), [PutBucketAcl](#), and [GetBucketVersioning](#) actions.

Enabling CloudTrail event logging for S3 buckets and objects

You can use CloudTrail data events to get information about bucket and object-level requests in Amazon S3. To enable CloudTrail data events for all of your buckets or for a list of specific buckets, you must [create a trail manually in CloudTrail](#).

Note

- The default setting for CloudTrail is to find only management events. Check to ensure that you have the data events enabled for your account.
- With an S3 bucket that is generating a high workload, you could quickly generate thousands of logs in a short amount of time. Be mindful of how long you choose to enable CloudTrail data events for a busy bucket.

CloudTrail stores Amazon S3 data event logs in an S3 bucket of your choosing. Consider using a bucket in a separate AWS account to better organize events from multiple buckets that you might own into a central place for easier querying and analysis. AWS Organizations helps you create an AWS account that is linked to the account that owns the bucket that you're monitoring. For more information, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*.

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors to log data events for objects stored in general purpose buckets. To log data events for objects stored in directory buckets, you must use advanced event selectors. For more information, see [Logging with AWS CloudTrail for S3 Express One Zone](#).

When you create a trail in the CloudTrail console using advanced event selectors, in the data events section, you can choose **Log all events** for the **Log selector template** to log all object-level events. When you create a trail in the CloudTrail console using basic event selectors, in the data events section, you can select the **Select all S3 buckets in your account** check box to log all object-level events.

Note

- It's a best practice to create a lifecycle configuration for your AWS CloudTrail data event bucket. Configure the lifecycle configuration to periodically remove log files after the period of time you believe you need to audit them. Doing so reduces the amount of data

that Athena analyzes for each query. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

- For more information about logging format, see [Logging Amazon S3 API calls using AWS CloudTrail](#).
- For examples of how to query CloudTrail logs, see the AWS *Big Data Blog* post [Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena](#).

Enable logging for objects in a bucket using the console

You can use the Amazon S3 console to configure an AWS CloudTrail trail to log data events for objects in an S3 bucket. CloudTrail supports logging Amazon S3 object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for S3 buckets that you specify, or to log data events for all the Amazon S3 buckets in your AWS account. For more information, see [Logging Amazon S3 API calls using AWS CloudTrail](#).

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all bucket-level actions are populated in the CloudTrail event history. For more information about the Amazon S3 bucket-level API actions tracked by CloudTrail logging, see [Amazon S3 bucket-level actions that are tracked by CloudTrail logging](#). For more information about how to query CloudTrail logs, see the AWS Knowledge Center article about [using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs](#).

To configure a trail to log data events for an S3 bucket, you can use either the AWS CloudTrail console or the Amazon S3 console. If you are configuring a trail to log data events for all the Amazon S3 buckets in your AWS account, it's easier to use the CloudTrail console. For information about using the CloudTrail console to configure a trail to log S3 data events, see [Data events](#) in the *AWS CloudTrail User Guide*.

Important

Additional charges apply for data events. For more information, see [AWS CloudTrail pricing](#).

The following procedure shows how to use the Amazon S3 console to configure a CloudTrail trail to log data events for an S3 bucket.

To enable CloudTrail data events logging for objects in an S3 general purpose bucket or in an S3 directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket.
3. Choose **Properties**.
4. Under **AWS CloudTrail data events**, choose **Configure in CloudTrail**.

You can create a new CloudTrail trail or reuse an existing trail and configure Amazon S3 data events to be logged in your trail. For information about how to create trails in the CloudTrail console, see [Creating and updating a trail with the console](#) in the *AWS CloudTrail User Guide*. For information about how to configure Amazon S3 data event logging in the CloudTrail console, see [Logging data events for Amazon S3 Objects](#) in the *AWS CloudTrail User Guide*.

 **Note**

If you use the CloudTrail console or the Amazon S3 console to configure a trail to log data events for an S3 bucket, the Amazon S3 console shows that object-level logging is enabled for the bucket.

To disable CloudTrail data events logging for objects in an S3 bucket

1. Sign in to the AWS Management Console and open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
2. In the left navigation pane, choose **Trails**.
3. Choose the name of the trail that you created to log events for your bucket.
4. On the details page for your trail, choose **Stop logging** in the upper-right corner.
5. In the dialog box that appears, choose **Stop logging**.

For information about enabling object-level logging when you create an S3 bucket, see [Creating a bucket](#).

For more information about CloudTrail logging with S3 buckets, see the following topics:

- [Viewing the properties for an S3 bucket](#)
- [Logging Amazon S3 API calls using AWS CloudTrail](#)
- [Working with CloudTrail Log Files in the AWS CloudTrail User Guide](#)

Identifying Amazon S3 requests using CloudTrail

In Amazon S3, you can identify requests using an AWS CloudTrail event log. AWS CloudTrail is the preferred way of identifying Amazon S3 requests, but if you are using Amazon S3 server access logs, see [the section called “Identifying S3 requests”](#).

Topics

- [Identifying requests made to Amazon S3 in a CloudTrail log](#)
- [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#)
- [Identifying access to S3 objects by using CloudTrail](#)

Identifying requests made to Amazon S3 in a CloudTrail log

After you set up CloudTrail to deliver events to a bucket, you should start to see objects go to your destination bucket on the Amazon S3 console. These are formatted as follows:

`s3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/Region/yyyy/mm/dd`

Events logged by CloudTrail are stored as compressed, gzipped JSON objects in your S3 bucket. To efficiently find requests, you should use a service like Amazon Athena to index and query the CloudTrail logs.

For more information about CloudTrail and Athena, see [Creating the table for AWS CloudTrail logs in Athena using partition projection](#) in the *Amazon Athena User Guide*.

Identifying Amazon S3 Signature Version 2 requests by using CloudTrail

You can use a CloudTrail event log to identify which API signature version was used to sign a request in Amazon S3. This capability is important because support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use *Signature Version 4* signing.

We *strongly* recommend that you use CloudTrail to help determine whether any of your workflows are using Signature Version 2 signing. Remediate them by upgrading your libraries and code to use Signature Version 4 instead to prevent any impact to your business.

For more information, see [Announcement: AWS CloudTrail for Amazon S3 adds new fields for enhanced security auditing](#) in AWS re:Post.

Note

CloudTrail events for Amazon S3 include the signature version in the request details under the key name of 'additionalEventData'. To find the signature version on requests made for objects in Amazon S3 such as GET, PUT, and DELETE requests, you must enable CloudTrail data events. (This feature is turned off by default.)

AWS CloudTrail is the preferred method for identifying Signature Version 2 requests. If you're using Amazon S3 server-access logs, see [Identifying Signature Version 2 requests by using Amazon S3 access logs](#).

Topics

- [Athena query examples for identifying Amazon S3 Signature Version 2 requests](#)
- [Partitioning Signature Version 2 data](#)

Athena query examples for identifying Amazon S3 Signature Version 2 requests

Example — Select all Signature Version 2 events, and print only EventTime, S3_Action, Request_Parameters, Region, SourceIP, and UserAgent

In the following Athena query, replace `s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table` with your Athena details, and increase or remove the limit as needed.

```
SELECT EventTime, EventName as S3_Action, requestParameters as Request_Parameters,  
awsregion as AWS_Region, sourceipaddress as Source_IP, useragent as User_Agent  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE eventsource='s3.amazonaws.com'  
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
LIMIT 10;
```

Example — Select all requesters that are sending Signature Version 2 traffic

```
SELECT useridentity.arn, Count(requestid) as RequestCount
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE eventsource='s3.amazonaws.com'
    and json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
Group by useridentity.arn
```

Partitioning Signature Version 2 data

If you have a large amount of data to query, you can reduce the costs and running time of Athena by creating a partitioned table.

To do this, create a new table with partitions as follows.

```
CREATE EXTERNAL TABLE s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table_partitioned(  
    eventversion STRING,  
    userIdentity STRUCT<  
        type:STRING,  
        principalid:STRING,  
        arn:STRING,  
        accountid:STRING,  
        invokedby:STRING,  
        accesskeyid:STRING,  
        userName:STRING,  
        sessioncontext:STRUCT<  
            attributes:STRUCT<  
                mfaauthenticated:STRING,  
                creationdate:STRING>,  
            sessionIssuer:STRUCT<  
                type:STRING,  
                principalId:STRING,  
                arn:STRING,  
                accountId:STRING,  
                userName:STRING>  
        >  
    >,  
    eventTime STRING,  
    eventSource STRING,
```

```
eventName STRING,  
awsRegion STRING,  
sourceIpAddress STRING,  
userAgent STRING,  
errorCode STRING,  
errorMessage STRING,  
requestParameters STRING,  
responseElements STRING,  
additionalEventData STRING,  
requestId STRING,  
eventId STRING,  
resources ARRAY<STRUCT<ARN:STRING,accountId: STRING,type:STRING>>,  
eventType STRING,  
apiVersion STRING,  
readOnly STRING,  
recipientAccountId STRING,  
serviceEventDetails STRING,  
sharedEventID STRING,  
vpcEndpointId STRING  
)  
PARTITIONED BY (region string, year string, month string, day string)  
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'  
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'  
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'  
LOCATION 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/';
```

Then, create the partitions individually. You can't get results from dates that you haven't created.

```
ALTER TABLE s3\_cLOUDTRAIL\_EVENTS\_DB.cLOUDTRAIL\_TABLE_partitioned ADD  
PARTITION (region= 'us-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-east-1/2019/02/19/'  
PARTITION (region= 'us-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-1/2019/02/19/'  
PARTITION (region= 'us-west-2', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-2/2019/02/19/'  
PARTITION (region= 'ap-southeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-1/2019/02/19/'  
PARTITION (region= 'ap-southeast-2', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-2/2019/02/19/'  
PARTITION (region= 'ap-northeast-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-northeast-1/2019/02/19/'
```

```
PARTITION (region= 'eu-west-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/eu-west-1/2019/02/19/'  
PARTITION (region= 'sa-east-1', year= '2019', month= '02', day= '19') LOCATION  
's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/sa-east-1/2019/02/19/';
```

You can then make the request based on these partitions, and you don't need to load the full bucket.

```
SELECT useridentity.arn,  
Count(requestid) AS RequestCount  
FROM s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table_partitioned  
WHERE eventsource='s3.amazonaws.com'  
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'  
AND region='us-east-1'  
AND year='2019'  
AND month='02'  
AND day='19'  
Group by useridentity.arn
```

Identifying access to S3 objects by using CloudTrail

You can use your AWS CloudTrail event logs to identify Amazon S3 object access requests for data events such as GetObject, DeleteObject, and PutObject, and discover additional information about those requests.

The following example shows how to get all PUT object requests for Amazon S3 from an AWS CloudTrail event log.

Topics

- [Athena query examples for identifying Amazon S3 object access requests](#)

Athena query examples for identifying Amazon S3 object access requests

In the following Athena query examples, replace

s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table with your Athena details, and modify the date range as needed.

Example — Select all events that have PUT object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
  eventName = 'PutObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all events that have GET object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table
WHERE
  eventName = 'GetObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all anonymous requester events to a bucket in a certain period and print only EventTime, EventName, EventSource, SourceIP, UserAgent, BucketName, UserARN, and AccountID

```
SELECT
```

```
eventTime,  
eventName,  
eventSource,  
sourceIpAddress,  
userAgent,  
json_extract_scalar(requestParameters, '$.bucketName') as bucketName,  
userIdentity.arn as userArn,  
userIdentity.accountId  
FROM  
s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE  
userIdentity.accountId = 'anonymous'  
AND eventTime BETWEEN '2019-07-05T00:00:00Z' AND '2019-07-06T00:00:00Z'
```

Example — Identify all requests that required an ACL for authorization

The following Amazon Athena query example shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. If the request required an ACL for authorization, the `aclRequired` value in `additionalEventData` is Yes. If no ACLs were required, `aclRequired` is not present. You can use this information to migrate those ACL permissions to the appropriate bucket policies. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

```
SELECT  
eventTime,  
eventName,  
eventSource,  
sourceIpAddress,  
userAgent,  
userIdentity.arn as userArn,  
json_extract_scalar(requestParameters, '$.bucketName') as bucketName,  
json_extract_scalar(requestParameters, '$.key') as object,  
json_extract_scalar(additionalEventData, '$.aclRequired') as aclRequired  
FROM  
s3_cLOUDTRAIL_EVENTS_DB.cloudtrail_table  
WHERE  
json_extract_scalar(additionalEventData, '$.aclRequired') = 'Yes'  
AND eventTime BETWEEN '2022-05-10T00:00:00Z' AND '2022-08-10T00:00:00Z'
```

Note

- These query examples can also be useful for security monitoring. You can review the results for PutObject or GetObject calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.

If you are using Amazon S3 server access logs, see [Identifying object access requests by using Amazon S3 access logs](#).

Logging requests with server access logging

Server access logging provides detailed records for the requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

Note

Server access logs don't record information about wrong-Region redirect errors for Regions that launched after March 20, 2019. Wrong-Region redirect errors occur when a request for an object or bucket is made outside the Region in which the bucket exists.

How do I enable log delivery?

To enable log delivery, perform the following basic steps. For details, see [Enabling Amazon S3 server access logging](#).

1. **Provide the name of the destination bucket** (also known as a *target bucket*). This bucket is where you want Amazon S3 to save the access logs as objects. Both the source and destination buckets must be in the same AWS Region and owned by the same account. The destination bucket must not have an S3 Object Lock default retention period configuration. The destination bucket must also not have Requester Pays enabled.

You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. But for simpler log management, we recommend that you save access logs in a different bucket.

When your source bucket and destination bucket are the same bucket, additional logs are created for the logs that are written to the bucket, which creates an infinite loop of logs. We do not recommend doing this because it could result in a small increase in your storage billing. In addition, the extra logs about logs might make it harder to find the log that you are looking for.

If you choose to save access logs in the source bucket, we recommend that you specify a destination prefix (also known as a *target prefix*) for all log object keys. When you specify a prefix, all the log object names begin with a common string, which makes the log objects easier to identify.

2. **(Optional) Assign a destination prefix to all Amazon S3 log object keys.** The destination prefix (also known as a *target prefix*) makes it simpler for you to locate the log objects. For example, if you specify the prefix value logs/, each log object that Amazon S3 creates begins with the logs/ prefix in its key, for example:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value logs, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

Prefixes are also useful to distinguish between source buckets when multiple buckets log to the same destination bucket.

This prefix can also help when you delete the logs. For example, you can set a lifecycle configuration rule for Amazon S3 to delete objects with a specific prefix. For more information, see [Deleting Amazon S3 log files](#).

3. **(Optional) Set permissions so that others can access the generated logs.** By default, only the bucket owner always has full access to the log objects. If your destination bucket uses the Bucket owner enforced setting for S3 Object Ownership to disable access control lists (ACLs), you can't grant permissions in destination grants (also known as *target grants*) that use ACLs. However, you can update your bucket policy for the destination bucket to grant access to others.

For more information, see [Identity and Access Management for Amazon S3](#) and [Permissions for log delivery](#).

4. (Optional) Set a log object key format for the log files. You have two options for the log object key format (also known as the *target object key format*):

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the prefix, your log objects are named like this:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For example, if you specify logs/ as the target prefix, your log objects are named like this:

```
logs/123456789012/us-west-2/amzn-s3-demo-source-bucket/2023/03/01/2023-03-01-21-32-16-E568B2907131C0C0
```

For delivery time delivery, the time in the log file names corresponds to the delivery time for the log files.

For event time delivery, the year, month, and day correspond to the day on which the event occurred, and the hour, minutes and seconds are set to 00 in the key. The logs delivered in these log files are for a specific day only.

If you're configuring your logs through the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, use TargetObjectKeyFormat to specify the log object key format.

To specify non-date-based partitioning, use SimplePrefix. To specify data-based partitioning,

use `PartitionedPrefix`. If you use `PartitionedPrefix`, use `PartitionDataSource` to specify either `EventTime` or `DeliveryTime`.

For `SimplePrefix`, the log file key format appears as follows:

```
[TargetPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For `PartitionedPrefix` with event time or delivery time, the log file key format appears as follows:

```
[TargetPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/  
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

Log object key format

Amazon S3 uses the following object key formats for the log objects that it uploads in the destination bucket:

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/  
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

In the log object key, `YYYY`, `MM`, `DD`, `hh`, `mm`, and `ss` are the digits of the year, month, day, hour, minute, and seconds (respectively). These dates and times are in Coordinated Universal Time (UTC).

A log file delivered at a specific time can contain records written at any point before that time. There is no way to know whether all log records for a certain time interval have been delivered or not.

The UniqueString component of the key is there to prevent overwriting of files. It has no meaning, and log processing software should ignore it.

How are logs delivered?

Amazon S3 periodically collects access log records, consolidates the records in log files, and then uploads log files to your destination bucket as log objects. If you enable logging on multiple source buckets that identify the same destination bucket, the destination bucket will have access logs for all those source buckets. However, each log object reports access log records for a specific source bucket.

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. We recommend that you update the bucket policy on the destination bucket to grant access to the logging service principal (`logging.s3.amazonaws.com`) for access log delivery. You can also grant access for access log delivery to the S3 log delivery group through your bucket access control list (ACL). However, granting access to the S3 log delivery group by using your bucket ACL is not recommended.

When you enable server access logging and grant access for access log delivery through your destination bucket policy, you must update the policy to allow `s3:PutObject` access for the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the destination bucket policy to grant these permissions to the logging service principal. For more information about granting permissions for server access log delivery, see [Permissions for log delivery](#).

 **Note**

S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. You must update the bucket policy on the destination bucket to grant access to the logging service principal. For more information about Object Ownership, see [Grant access to the S3 log delivery group for server access logging](#).

Best-effort server log delivery

Server access log records are delivered on a best-effort basis. Most requests for a bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. It is possible that you might even see a duplication of a log record. The purpose of server logs is to give you an idea of the nature of traffic against your bucket. Although log records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

Because of the best-effort nature of server logging, your usage reports might include one or more access requests that do not appear in a delivered server log. You can find these usage reports under **Cost & usage reports** in the AWS Billing and Cost Management console.

Bucket logging status changes take effect over time

Changes to the logging status of a bucket take time to actually affect the delivery of log files. For example, if you enable logging for a bucket, some requests made in the following hour might be logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. In all cases, the new settings eventually take effect without any further action on your part.

For more information about logging and log files, see the following sections:

Topics

- [Enabling Amazon S3 server access logging](#)
- [Amazon S3 server access log format](#)
- [Deleting Amazon S3 log files](#)
- [Using Amazon S3 server access logs to identify requests](#)
- [Troubleshoot server access logging](#)

Enabling Amazon S3 server access logging

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

By default, Amazon S3 doesn't collect server access logs. When you enable logging, Amazon S3 delivers access logs for a source bucket to a destination bucket (also known as a *target bucket*) that you choose. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

An access log record contains details about the requests that are made to a bucket. This information can include the request type, the resources that are specified in the request, and the time and date that the request was processed. For more information about logging basics, see [Logging requests with server access logging](#).

Important

- There is no extra charge for enabling server access logging on an Amazon S3 bucket. However, any log files that the system delivers to you will accrue the usual charges for storage. (You can delete the log files at any time.) We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files.
- Your destination bucket should not have server access logging enabled. You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. However, delivering logs to the source bucket will cause an infinite loop of logs and is not recommended. For simpler log management, we recommend that you save access logs in a different bucket. For more information, see [How do I enable log delivery?](#)
- S3 buckets that have S3 Object Lock enabled can't be used as destination buckets for server access logs. Your destination bucket must not have a default retention period configuration.
- The destination bucket must not have Requester Pays enabled.
- You can use [default bucket encryption](#) on the destination bucket *only* if you use server-side encryption with Amazon S3 managed keys (SSE-S3), which uses the 256-bit

Advanced Encryption Standard (AES-256). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported.

You can enable or disable server access logging by using the Amazon S3 console, Amazon S3 API, the AWS Command Line Interface (AWS CLI), or AWS SDKs.

Permissions for log delivery

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. For access log delivery, you must grant the logging service principal (`logging.s3.amazonaws.com`) access to your destination bucket.

To grant permissions to Amazon S3 for log delivery, you can use either a bucket policy or bucket access control lists (ACLs), depending on your destination bucket's S3 Object Ownership settings. However, we recommend that you use a bucket policy instead of ACLs.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. In this case, you must update the bucket policy for the destination bucket to grant access to the logging service principal. You can't update your bucket ACL to grant access to the S3 log delivery group. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration.

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For more information about Object Ownership, see [Controlling ownership of objects and disabling ACLs for your bucket](#). When you create new buckets, ACLs are disabled by default.

Granting access by using a bucket policy

To grant access by using the bucket policy on the destination bucket, update the bucket policy to grant the `s3:PutObject` permission to the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination bucket to grant this permission to the logging service principal. If you enable server access logging programmatically, you must manually update the bucket policy for the destination bucket to grant access to the logging service principal.

For an example bucket policy that grants access to the logging service principal, see [the section called "Grant permissions to the logging service principal by using a bucket policy"](#).

Granting access by using bucket ACLs

You can alternately use bucket ACLs to grant access for access log delivery. You add a grant entry to the bucket ACL that grants WRITE and READ_ACP permissions to the S3 log delivery group. However, granting access to the S3 log delivery group by using bucket ACLs is not recommended. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#). For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see [Grant access to the S3 log delivery group for server access logging](#). For an example ACL that grants access to the logging service principal, see [the section called “Grant permissions to the log delivery group by using a bucket ACL”](#).

Grant permissions to the logging service principal by using a bucket policy

This example bucket policy grants the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *EXAMPLE-LOGGING-PREFIX* is the optional destination prefix (also known as a *target prefix*) that you want to use for your log objects. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

Note

If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

            "aws:SourceAccount": "SOURCE-ACCOUNT-ID"  
        }  
    }  
}  
]
```

Grant permissions to the log delivery group by using a bucket ACL

Note

As a security best practice, Amazon S3 disables access control lists (ACLs) by default in all new buckets. For more information about ACL permissions in the Amazon S3 console, see [Configuring ACLs](#).

Although we do not recommend this approach, you can grant permissions to the log delivery group by using a bucket ACL. However, if the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination grants (also known as *target grants*) in your [PutBucketLogging](#) configuration. Instead, you must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

In the bucket ACL, the log delivery group is represented by the following URL:

```
http://acs.amazonaws.com/groups/s3/LogDelivery
```

To grant WRITE and READ_ACP (ACL read) permissions, add the following grants to the destination bucket ACL:

```
<Grant>  
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">  
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>  
  </Grantee>
```

```
<Permission>WRITE</Permission>
</Grant>
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
  </Grantee>
  <Permission>READ_ACP</Permission>
</Grant>
```

For examples of adding ACL grants programmatically, see [Configuring ACLs](#).

Important

When you enable Amazon S3 server access logging by using AWS CloudFormation on a bucket and you're using ACLs to grant access to the S3 log delivery group, you must also add "AccessControl": "LogDeliveryWrite" to your CloudFormation template. Doing so is important because you can grant those permissions only by creating an ACL for the bucket, but you can't create custom ACLs for buckets in CloudFormation. You can use only canned ACLs with CloudFormation.

To enable server access logging

To enable server access logging by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, and AWS CLI, use the following procedures.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable server access logging for.
4. Choose **Properties**.
5. In the **Server access logging** section, choose **Edit**.
6. Under **Server access logging**, choose **Enable**.
7. Under **Destination bucket**, specify a bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

Note

Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects. For example, if you specify the prefix value logs/, each log object that Amazon S3 creates begins with the logs/ prefix in its key, as follows:

logs/2013-11-01-21-32-16-E568B2907131C0C0

If you specify the prefix value logs, the log object appears as follows:

logs2013-11-01-21-32-16-E568B2907131C0C0

8. Under **Log object key format**, do one of the following:

- To choose non-date-based partitioning, choose **[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**.
- To choose date-based partitioning, choose **[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**, then choose **S3 event time** or **Log file delivery time**.

9. Choose **Save changes**.

When you enable server access logging on a bucket, the console both enables logging on the source bucket and updates the bucket policy for the destination bucket to grant the s3:PutObject permission to the logging service principal (logging.s3.amazonaws.com). For more information about this bucket policy, see [Grant permissions to the logging service principal by using a bucket policy](#).

You can view the logs in the destination bucket. After you enable server access logging, it might take a few hours before the logs are delivered to the target bucket. For more information about how and when logs are delivered, see [How are logs delivered?](#)

For more information, see [Viewing the properties for an S3 bucket](#).

Using the REST API

To enable logging, you submit a [PutBucketLogging](#) request to add the logging configuration on the source bucket. The request specifies the destination bucket (also known as a *target bucket*) and, optionally, the prefix to be used with all log object keys.

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket and *Logs/* as the prefix.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>Logs/</TargetPrefix>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket, *Logs/* as the prefix, and EventTime as the log object key format.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>Logs/</TargetPrefix>
    <TargetObjectKeyFormat>
      <PartitionedPrefix>
        <PartitionDataSource>EventTime</PartitionDataSource>
      </PartitionedPrefix>
    </TargetObjectKeyFormat>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The log objects are written and owned by the S3 log delivery account, and the bucket owner is granted full permissions on the log objects. You can optionally use destination grants (also known as *target grants*) to grant permissions to other users so that they can access the logs. For more information, see [PutBucketLogging](#).

Note

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't use destination grants to grant permissions to other users. To grant permissions to

others, you can update the bucket policy on the destination bucket. For more information, see [Permissions for log delivery](#).

To retrieve the logging configuration on a bucket, use the [GetBucketLogging](#) API operation.

To delete the logging configuration, you send a PutBucketLogging request with an empty BucketLoggingStatus:

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
</BucketLoggingStatus>
```

To enable logging on a bucket, you can use either the Amazon S3 API or the AWS SDK wrapper libraries.

Using the AWS SDKs

The following examples enable logging on a bucket. You must create two buckets, a source bucket and a destination (target) bucket. The examples update the bucket ACL on the destination bucket first. They then grant the log delivery group the necessary permissions to write logs to the destination bucket, and then they enable logging on the source bucket.

These examples won't work on destination buckets that use the Bucket owner enforced setting for Object Ownership.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your [PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (logging.s3.amazonaws.com). For more information, see [Permissions for log delivery](#).

```

```
        .build();
    s3Client.putBucketLogging(PutBucketLoggingRequest.builder()
        .bucket(sourceBucketName)
        .bucketLoggingStatus(bucketLoggingStatus)
        .build());
}

}
```

Using the AWS CLI

We recommend that you create a dedicated logging bucket in each AWS Region that you have S3 buckets in. Then have your Amazon S3 access logs delivered to that S3 bucket. For more information and examples, see [put-bucket-logging](#) in the *AWS CLI Reference*.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your [PutBucketLogging](#) configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see [Permissions for log delivery](#).

Example — Enable access logs with five buckets across two Regions

In this example, you have the following five buckets:

- `amzn-s3-demo-source-bucket-us-east-1`
- `amzn-s3-demo-source-bucket1-us-east-1`
- `amzn-s3-demo-source-bucket2-us-east-1`
- `amzn-s3-demo-bucket1-us-west-2`
- `amzn-s3-demo-bucket2-us-west-2`

Note

The final step of the following procedure provides example bash scripts that you can use to create your logging buckets and enable server access logging on these buckets. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in the following procedure.

1. Create two logging destination buckets in the US West (Oregon) and US East (N. Virginia) Regions and give them the following names:
 - *amzn-s3-demo-destination-bucket-logs-us-east-1*
 - *amzn-s3-demo-destination-bucket1-logs-us-west-2*
2. Later in these steps, you will enable server access logging as follows:
 - *amzn-s3-demo-source-bucket-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket-us-east-1*
 - *amzn-s3-demo-source-bucket1-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket1-us-east-1*
 - *amzn-s3-demo-source-bucket2-us-east-1* logs to the S3 bucket *amzn-s3-demo-destination-bucket-logs-us-east-1* with the prefix *amzn-s3-demo-source-bucket2-us-east-1*
 - *amzn-s3-demo-bucket1-us-west-2* logs to the S3 bucket *amzn-s3-demo-destination-bucket1-logs-us-west-2* with the prefix *amzn-s3-demo-bucket1-us-west-2*
 - *amzn-s3-demo-bucket2-us-west-2* logs to the S3 bucket *amzn-s3-demo-destination-bucket1-logs-us-west-2* with the prefix *amzn-s3-demo-bucket2-us-west-2*
3. For each destination logging bucket, grant permissions for server access log delivery by using a bucket ACL or a bucket policy:
 - **Update the bucket policy** (Recommended) – To grant permissions to the logging service principal, use the following put-bucket-policy command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination bucket.

```
aws s3api put-bucket-policy --bucket amzn-s3-demo-destination-bucket-logs --  
policy file://policy.json
```

Policy.json is a JSON document in the current folder that contains the following bucket policy. To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket-logs* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-*

bucket is the source bucket. **SOURCE-ACCOUNT-ID** is the AWS account that owns the source bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "S3ServerAccessLogsPolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "logging.s3.amazonaws.com"  
            },  
            "Action": [  
                "s3:PutObject"  
            ],  
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket-logs/*",  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-bucket"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"  
                }  
            }  
        }  
    ]  
}
```

- **Update the bucket ACL** – To grant permissions to the S3 log delivery group, use the following put-bucket-acl command. Replace **amzn-s3-demo-destination-bucket-logs** with the name of your destination (target) bucket.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-destination-bucket-logs --  
grant-write URI=http://acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp  
URI=http://acs.amazonaws.com/groups/s3/LogDelivery
```

4. Then, create a logging.json file that contains your logging configuration (based on one of the three examples that follow). After you create the logging.json file, you can apply

the logging configuration by using the following put-bucket-logging command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-logging --bucket amzn-s3-demo-destination-bucket-logs --  
bucket-logging-status file://logging.json
```

 **Note**

Instead of using this put-bucket-logging command to apply the logging configuration on each destination bucket, you can use one of the bash scripts provided in the next step. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in this procedure.

The `logging.json` file is a JSON document in the current folder that contains your logging configuration. If a destination bucket uses the Bucket owner enforced setting for Object Ownership, your logging configuration can't contain destination (target) grants. For more information, see [Permissions for log delivery](#).

Example – `logging.json` without destination (target) grants

The following example `logging.json` file doesn't contain destination (target) grants. Therefore, you can apply this configuration to a destination (target) bucket that uses the Bucket owner enforced setting for Object Ownership.

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
        "TargetPrefix": "amzn-s3-demo-destination-bucket/"  
    }  
}
```

Example – logging.json with destination (target) grants

The following example logging.json file contains destination (target) grants.

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't include destination (target) grants in your [PutBucketLogging](#) configuration. For more information, see [Permissions for log delivery](#).

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",  
        "TargetGrants": [  
            {  
                "Grantee": {  
                    "Type": "AmazonCustomerByEmail",  
                    "EmailAddress": "user@example.com"  
                },  
                "Permission": "FULL_CONTROL"  
            }  
        ]  
    }  
}
```

Example – logging.json with the log object key format set to S3 event time

The following logging.json file changes the log object key format to S3 event time. For more information about setting the log object key format, see [the section called “How do I enable log delivery?”](#)

```
{  
    "LoggingEnabled": {  
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",  
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",  
        "TargetObjectKeyFormat": {  
            "PartitionedPrefix": {  
                "PartitionDataSource": "EventTime"  
            }  
        }  
    }  
}
```

```
    }  
}  
}
```

5. Use one of the following bash scripts to add access logging for all the buckets in your account. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket, and replace *us-west-2* with the name of the Region that your buckets are located in.

 **Note**

This script works only if all of your buckets are in the same Region. If you have buckets in multiple Regions, you must adjust the script.

Example – Grant access with bucket policies and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'  
region='us-west-2'  
  
# Create the logging bucket.  
aws s3 mb s3://$loggingBucket --region $region  
  
aws s3api put-bucket-policy --bucket $loggingBucket --policy file://policy.json  
  
# List the buckets in this account.  
buckets="$(aws s3 ls | awk '{print $3}')"  
  
# Put a bucket logging configuration on each bucket.  
for bucket in $buckets  
do  
    # This if statement excludes the logging bucket.  
    if [ "$bucket" != "$loggingBucket" ] ; then  
        continue;  
    fi  
    printf '{  
        "LoggingEnabled": {  
            "TargetBucket": "%s",
```

```
        "TargetPrefix": "%s/"
    }
}' "$loggingBucket" "$bucket" > logging.json
aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
echo "$bucket done"
done

rm logging.json

echo "Complete"
```

Example – Grant access with bucket ACLs and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-acl --bucket $loggingBucket --grant-write URI=http://
acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://
acs.amazonaws.com/groups/s3/LogDelivery

# List the buckets in this account.
buckets=$(aws s3 ls | awk '{print $3}')

# Put a bucket logging configuration on each bucket.
for bucket in $buckets
do
    # This if statement excludes the logging bucket.
    if [ "$bucket" != "$loggingBucket" ] ; then
        continue;
    fi
    printf '{
        "LoggingEnabled": {
            "TargetBucket": "%s",
            "TargetPrefix": "%s/"
        }
    }' "$loggingBucket" "$bucket" > logging.json
```

```
aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://  
logging.json  
echo "$bucket done"  
done  
  
rm logging.json  
  
echo "Complete"
```

Verifying your server access logs setup

After you enable server access logging, complete the following steps:

- Access the destination bucket and verify that the log files are being delivered. After the access logs are set up, Amazon S3 immediately starts capturing requests and logging them. However, it might take a few hours before the logs are delivered to the destination bucket. For more information, see [the section called “Bucket logging status changes take effect over time”](#) and [the section called “Best-effort server log delivery”](#).

You can also automatically verify log delivery by using Amazon S3 request metrics and setting up Amazon CloudWatch alarms for these metrics. For more information, see [Monitoring metrics with Amazon CloudWatch](#).

- Verify that you are able to open and read the contents of the log files.

For server access logging troubleshooting information, see [Troubleshoot server access logging](#).

Amazon S3 server access log format

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. You can use server access logs for the following purposes:

- Performing security and access audits
- Learning about your customer base
- Understanding your Amazon S3 bill

This section describes the format and other details about Amazon S3 server access log files.

Server access log files consist of a sequence of newline-delimited log records. Each log record represents one request and consists of space-delimited fields.

The following is an example log consisting of five log records.

```

Note

Any field can be set to - to indicate that the data was unknown or unavailable, or that the field was not applicable to this request.

Topics

- [Log record fields](#)
- [Additional logging for copy operations](#)
- [Custom access log information](#)
- [Programming considerations for extensible server access log format](#)

Log record fields

The following list describes the log record fields.

Bucket Owner

The canonical user ID of the owner of the source bucket. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that the request was processed against. If the system receives a malformed request and cannot determine the bucket, the request will not appear in any server access log.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%b/%Y:%H:%M:%S %z]

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field returns the requester's IAM user name along with the AWS account that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request.

Example entry

3E57427F33A59F07

Operation

The operation listed here is declared as SOAP.*operation*, REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or BATCH.DELETE.OBJECT, or S3.action.resource_type for [S3 Lifecycle and logging](#).

Example entry

REST.PUT.OBJECT

Key

The key (object name) part of the request.

Example entry

/photos/2019/08/puppy.jpg

Request-URI

The Request-URI part of the HTTP request message.

Example Entry

"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar HTTP/1.1"

HTTP status

The numeric HTTP status code of the response.

Example entry

200

Error Code

The Amazon S3 [Error responses](#), or - if no error occurred.

Example entry

NoSuchBucket

Bytes Sent

The number of response bytes sent, excluding HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

10

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID in the request, or - if the operation doesn't take a `versionId` parameter.

Example entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzMHyFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request or a - for unauthenticated requests.

Example entry

```
SigV2
```

Cipher Suite

The Secure Sockets Layer (SSL) cipher that was negotiated for an HTTPS request or a - for HTTP.

Example entry

ECDHE-RSA-AES128-GCM-SHA256

Authentication Type

The type of request authentication used: AuthHeader for authentication headers, QueryString for query string (presigned URL), or a - for unauthenticated requests.

Example entry

AuthHeader

Host Header

The endpoint used to connect to Amazon S3.

Example entry

s3.us-west-2.amazonaws.com

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

TLSv1.2

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see [Using Amazon S3 access points](#). For more information about ARNs, see [Amazon Resource Name \(ARN\) in the AWS Reference Guide](#).

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Additional logging for copy operations

A copy operation involves a GET and a PUT. For that reason, we log two records when performing a copy operation. The previous section describes the fields related to the PUT part of the operation. The following list describes the fields in the record that relate to the GET part of the copy operation.

Bucket Owner

The canonical user ID of the bucket that stores the object being copied. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see [AWS account identifiers](#) in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see [Finding the canonical user ID for your AWS account](#).

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that stores the object that's being copied.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: [%d/%B/%Y:%H:%M:%S %z]

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field will return the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request.

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as SOAP.*operation*,
REST.*HTTP_method.resource_type*, WEBSITE.*HTTP_method.resource_type*, or
BATCH.DELETE.OBJECT.

Example entry

```
REST.COPY.OBJECT_GET
```

Key

The key (object name) of the object being copied, or - if the operation doesn't take a key parameter.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The Request-URI part of the HTTP request message.

Example entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar"
```

HTTP status

The numeric HTTP status code of the GET portion of the copy operation.

Example entry

200

Error Code

The Amazon S3 [Error responses](#) of the GET portion of the copy operation, or - if no error occurred.

Example entry

NoSuchBucket

Bytes Sent

The number of response bytes sent, excluding the HTTP protocol overhead, or - if zero.

Example entry

2662992

Object Size

The total size of the object in question.

Example entry

3462992

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

70

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

10

Referer

The value of the HTTP Referer header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP User-Agent header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID of the object being copied, or - if the x-amz-copy-source header didn't specify a versionId parameter as part of the copy source.

Example Entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The x-amz-id-2 or Amazon S3 extended request ID.

Example entry

```
s9lzMHyFp76ZVxRcpX9+5cjAnEH2R0uNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request, or a `-` for unauthenticated requests.

Example entry

```
SigV4
```

Cipher Suite

The Secure Sockets Layer (SSL) cipher that was negotiated for an HTTPS request, or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query strings (presigned URLs), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint that was used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see [Legacy endpoints](#). For a complete

list of Amazon S3 Regions and endpoints, see [Amazon S3 endpoints and quotas](#) in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: TLSv1.1, TLSv1.2, TLSv1.3, or - if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a -. For more information about access points, see [Using Amazon S3 access points](#). For more information about ARNs, see [Amazon Resource Name \(ARN\)](#) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is Yes. If no ACLs were required, the string is -. For more information about ACLs, see [Access control list \(ACL\) overview](#). For more information about using the aclRequired field to disable ACLs, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Example entry

```
Yes
```

Custom access log information

You can include custom information to be stored in the access log record for a request. To do this, add a custom query-string parameter to the URL for the request. Amazon S3 ignores query-string

parameters that begin with x-, but includes those parameters in the access log record for the request, as part of the Request-URI field of the log record.

For example, a GET request for "s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-user=johndoe" works the same as the request for "s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg", except that the "x-user=johndoe" string is included in the Request-URI field for the associated log record. This functionality is available in the REST interface only.

Programming considerations for extensible server access log format

Occasionally, we might extend the access log record format by adding new fields to the end of each line. Therefore, make sure that any of your code that parses server access logs can handle trailing fields that it might not understand.

Deleting Amazon S3 log files

An Amazon S3 bucket with server access logging enabled can accumulate many server log objects over time. Your application might need these access logs for a specific period after they are created, and after that, you might want to delete them. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically queues these objects for deletion at the end of their life.

You can define a lifecycle configuration for a subset of objects in your S3 bucket by using a shared prefix. If you specified a prefix in your server access logging configuration, you can set a lifecycle configuration rule to delete log objects that have that prefix.

For example, suppose that your log objects have the prefix logs/. You can set a lifecycle configuration rule to delete all objects in the bucket that have the prefix logs/ after a specified period of time.

For more information about lifecycle configuration, see [Managing the lifecycle of objects](#).

For general information about server access logging, see [Logging requests with server access logging](#).

Using Amazon S3 server access logs to identify requests

You can identify Amazon S3 requests by using Amazon S3 server access logs.

Note

- To identify Amazon S3 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information. For more information, see [Identifying Amazon S3 requests using CloudTrail](#).
- Depending on how many access requests you get, analyzing your logs might require more resources or time than using CloudTrail data events.

Topics

- [Querying access logs for requests by using Amazon Athena](#)
- [Identifying Signature Version 2 requests by using Amazon S3 access logs](#)
- [Identifying object access requests by using Amazon S3 access logs](#)

Querying access logs for requests by using Amazon Athena

You can identify Amazon S3 requests with Amazon S3 access logs by using Amazon Athena.

Amazon S3 stores server access logs as objects in an S3 bucket. It is often easier to use a tool that can analyze the logs in Amazon S3. Athena supports analysis of S3 objects and can be used to query Amazon S3 access logs.

Example

The following example shows how you can query Amazon S3 server access logs in Amazon Athena. Replace the *user input placeholders* used in the following examples with your own information.

Note

To specify an Amazon S3 location in an Athena query, you must provide an S3 URI for the bucket where your logs are delivered to. This URI must include the bucket name and prefix in the following format: `s3://amzn-s3-demo-bucket1-logs/prefix/`

1. Open the Athena console at <https://console.aws.amazon.com/athena/>.

2. In the Query Editor, run a command similar to the following. Replace `s3_access_logs_db` with the name that you want to give to your database.

```
CREATE DATABASE s3_access_logs_db
```

 **Note**

It's a best practice to create the database in the same AWS Region as your S3 bucket.

3. In the Query Editor, run a command similar to the following to create a table schema in the database that you created in step 2. Replace `s3_access_logs_db.mybucket_logs` with the name that you want to give to your table. The STRING and BIGINT data type values are the access log properties. You can query these properties in Athena. For LOCATION, enter the S3 bucket and prefix path as noted earlier.

Date-based partitioning

```
CREATE EXTERNAL TABLE s3_access_logs_db.mybucket_logs(  
    `bucketowner` STRING,  
    `bucket_name` STRING,  
    `requestdatetime` STRING,  
    `remoteip` STRING,  
    `requester` STRING,  
    `requestid` STRING,  
    `operation` STRING,  
    `key` STRING,  
    `request_uri` STRING,  
    `httpstatus` STRING,  
    `errorcode` STRING,  
    `bytessent` BIGINT,  
    `objectsize` BIGINT,  
    `totaltime` STRING,  
    `turnaroundtime` STRING,  
    `referrer` STRING,  
    `useragent` STRING,  
    `versionid` STRING,  
    `hostid` STRING,  
    `sigv` STRING,  
    `ciphersuite` STRING,  
    `authtype` STRING,  
    `endpoint` STRING,
```

```

`tlsversion` STRING,
`accesspointarn` STRING,
`aclrequired` STRING)
PARTITIONED BY (
    `timestamp` string)
ROW FORMAT SERDE
    'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
    'input.regex'='([^\n]* ([^\n]*) \\[.*?]\\] ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n]*) ([^\n"]*)\"| -) (-|[0-9]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*)([^ ]*))?)?.*${1}'
STORED AS INPUTFORMAT
    'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
    'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
    's3://bucket-name/prefix-name/account-id/region/source-bucket-name/'
TBLPROPERTIES (
    'projection.enabled'='true',
    'projection.timestamp.format'='yyyy/MM/dd',
    'projection.timestamp.interval'='1',
    'projection.timestamp.interval.unit'='DAYS',
    'projection.timestamp.range'='2024/01/01,NOW',
    'projection.timestamp.type'='date',
    'storage.location.template'='s3://bucket-name/prefix-name/account-id/region/
source-bucket-name/${timestamp}')'

```

Non-date-based partitioning

```

CREATE EXTERNAL TABLE `s3_access_logs_db.mybucket_logs`(
    `bucketowner` STRING,
    `bucket_name` STRING,
    `requestdatetime` STRING,
    `remoteip` STRING,
    `requester` STRING,
    `requestid` STRING,
    `operation` STRING,
    `key` STRING,
    `request_uri` STRING,
    `httpstatus` STRING,
    `errorcode` STRING,

```

4. In the navigation pane, under **Database**, choose your database.
 5. Under **Tables**, choose **Preview table** next to your table name.

In the **Results** pane, you should see data from the server access logs, such as `bucketowner`, `bucket`, `requestdatetime`, and so on. This means that you successfully created the Athena table. You can now query the Amazon S3 server access logs.

Example — Show who deleted an object and when (timestamp, IP address, and IAM user)

```
SELECT requestdatetime, remoteip, requester, key  
FROM s3_access_logs_db.mybucket_logs  
WHERE key = 'images/picture.jpg' AND operation like '%DELETE%';
```

Example — Show all operations that were performed by an IAM user

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE requester='arn:aws:iam::123456789123:user/user_name';
```

Example — Show all operations that were performed on an object in a specific time period

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE Key='prefix/images/picture.jpg'
    AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
    BETWEEN parse_datetime('2017-02-18:07:00:00','yyyy-MM-dd:HH:mm:ss')
    AND parse_datetime('2017-02-18:08:00:00','yyyy-MM-dd:HH:mm:ss');
```

Example — Show how much data was transferred to a specific IP address in a specific time period

```
SELECT coalesce(SUM(bytessent), 0) AS bytessenttotal
FROM s3_access_logs_db.mybucket_logs
WHERE remoteip='192.0.2.1'
    AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
    BETWEEN parse_datetime('2022-06-01','yyyy-MM-dd')
    AND parse_datetime('2022-07-01','yyyy-MM-dd');
```

Note

To reduce the time that you retain your logs, you can create an S3 Lifecycle configuration for your server access logs bucket. Create lifecycle configuration rules to remove log files periodically. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#).

Identifying Signature Version 2 requests by using Amazon S3 access logs

Amazon S3 support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use Signature Version 4 signing. You can identify Signature Version 2 access requests by using Amazon S3 access logs.

Note

To identify Signature Version 2 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information than server access logs. For more information, see [Identifying Amazon S3 Signature Version 2 requests by using CloudTrail](#).

Example — Show all requesters that are sending Signature Version 2 traffic

```
SELECT requester, sigv, Count(sigv) as sigcount
FROM s3_access_logs_db.mybucket_logs
GROUP BY requester, sigv;
```

Identifying object access requests by using Amazon S3 access logs

You can use queries on Amazon S3 server access logs to identify Amazon S3 object access requests, for operations such as GET, PUT, and DELETE, and discover further information about those requests.

The following Amazon Athena query example shows how to get all PUT object requests for Amazon S3 from a server access log.

Example — Show all requesters that are sending PUT object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db
WHERE operation='REST.PUT.OBJECT' AND
parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all GET object requests for Amazon S3 from the server access log.

Example — Show all requesters that are sending GET object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db
WHERE operation='REST.GET.OBJECT' AND
parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all anonymous requests to your S3 buckets from the server access log.

Example — Show all anonymous requesters that are making requests to a bucket during a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE requester IS NULL AND
parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
AND
parse_datetime('2019-07-02:00:42:42', 'yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. You can use this information to migrate those ACL permissions to the appropriate bucket policies and disable ACLs. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see [Prerequisites for disabling ACLs](#).

Example — Identify all requests that required an ACL for authorization

```
SELECT bucket_name, requester, key, operation, aclrequired, requestdatetime
FROM s3_access_logs_db
```

```
WHERE aclrequired = 'Yes' AND
parse_datetime(requestdatetime, 'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-05-10:00:00:00', 'yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2022-08-10:00:00:00', 'yyyy-MM-dd:HH:mm:ss')
```

Note

- You can modify the date range as needed to suit your needs.
- These query examples might also be useful for security monitoring. You can review the results for PutObject or GetObject calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.
- If you are using AWS CloudTrail logs, see [Identifying access to S3 objects by using CloudTrail](#).

Troubleshoot server access logging

The following topics can help you troubleshoot issues that you might encounter when setting up logging with Amazon S3.

Topics

- [Common error messages when setting up logging](#)
- [Troubleshooting delivery failures](#)

Common error messages when setting up logging

The following common error messages can appear when you're enabling logging through the AWS Command Line Interface (AWS CLI) and AWS SDKs:

Error: Cross S3 location logging not allowed

If the destination bucket (also known as a *target bucket*) is in a different Region than the source bucket, a Cross S3 location logging not allowed error occurs. To resolve this error, make sure that the destination bucket configured to receive the access logs is in the same AWS Region and AWS account as the source bucket.

Error: The owner for the bucket to be logged and the target bucket must be the same

When you're enabling server access logging, this error occurs if the specified destination bucket belongs to a different account. To resolve this error, make sure that the destination bucket is in the same AWS account as the source bucket.

Note

We recommend that you choose a destination bucket that's different from the source bucket. When the source bucket and destination bucket are the same, additional logs are created for the logs that are written to the bucket, which can increase your storage bill. These extra logs about logs can also make it difficult to find the particular logs that you're looking for. For simpler log management, we recommend saving access logs in a different bucket. For more information, see [the section called "How do I enable log delivery?"](#).

Error: The target bucket for logging does not exist

The destination bucket must exist prior to setting the configuration. This error indicates that the destination bucket doesn't exist or can't be found. Make sure that the bucket name is spelled correctly, and then try again.

Error: Target grants not allowed for bucket owner enforced buckets

This error indicates that the destination bucket uses the Bucket owner enforced setting for S3 Object Ownership. The Bucket owner enforced setting doesn't support destination (target) grants. For more information, see [Permissions for log delivery](#).

Troubleshooting delivery failures

To avoid server access logging issues, make sure that you're following these best practices:

- **The S3 log delivery group has write access to the destination bucket** – The S3 log delivery group delivers server access logs to the destination bucket. A bucket policy or bucket access control list (ACL) can be used to grant write access to the destination bucket. However, we recommend that you use a bucket policy instead of an ACL. For more information about how to grant write access to your destination bucket, see [Permissions for log delivery](#).

Note

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, be aware of the following:

- ACLs are disabled and no longer affect permissions. This means that you can't update your bucket ACL to grant access to the S3 log delivery group. Instead, to grant access to the logging service principal, you must update the bucket policy for the destination bucket.
- You can't include destination grants in your PutBucketLogging configuration.

- **The bucket policy for the destination bucket allows access to the logs** – Check the bucket policy of the destination bucket. Search the bucket policy for any statements that contain "Effect": "Deny". Then, verify that the Deny statement isn't preventing access logs from being written to the bucket.
- **S3 Object Lock isn't enabled on the destination bucket** – Check if the destination bucket has Object Lock enabled. Object Lock blocks server access log delivery. You must choose a destination bucket that doesn't have Object Lock enabled.
- **Amazon S3 managed keys (SSE-S3) is selected if default encryption is enabled on the destination bucket** – You can use default bucket encryption on the destination bucket only if you use server-side encryption with Amazon S3 managed keys (SSE-S3). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported for server access logging destination buckets. For more information about how to enable default encryption, see [Configuring default encryption](#).
- **The destination bucket does not have Requester Pays enabled** – Using a Requester Pays bucket as the destination bucket for server access logging is not supported. To allow delivery of server access logs, disable the Requester Pays option on the destination bucket.
- **Review your AWS Organizations service control policies (SCPs) and resource control policies (RCPs)** – When you're using AWS Organizations, check the service control policies and resource control policies to make sure that Amazon S3 access is allowed. These policies specify the maximum permissions for principals and resources in the affected accounts. Search the policies for any statements that contain "Effect": "Deny" and verify that Deny statements aren't preventing any access logs from being written to the bucket. For more information, see [Authorization policies in AWS Organizations](#) in the *AWS Organizations User Guide*.

- **Allow some time for recent logging configuration changes to take effect** – Enabling server access logging for the first time, or changing the destination bucket for logs, requires time to fully take effect. It might take longer than an hour for all requests to be properly logged and delivered.

To check for log delivery failures, enable request metrics in Amazon CloudWatch. If the logs are not delivered within a few hours, look for the `4xxErrors` metric, which can indicate log delivery failures. For more information about enabling request metrics, see [the section called “Creating a metrics configuration for all objects”](#).

Monitoring metrics with Amazon CloudWatch

Amazon CloudWatch metrics for Amazon S3 can help you understand and improve the performance of applications that use Amazon S3. There are several ways that you can use CloudWatch with Amazon S3.

Daily storage metrics for buckets

Monitor bucket storage using CloudWatch, which collects and processes storage data from Amazon S3 into readable, daily metrics. These storage metrics for Amazon S3 are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor Amazon S3 requests to quickly identify and act on operational issues. The metrics are available at 1-minute intervals after some latency for processing. These CloudWatch metrics are billed at the same rate as the Amazon CloudWatch custom metrics. For information about CloudWatch pricing, see [Amazon CloudWatch pricing](#). To learn how to opt in to getting these metrics, see [CloudWatch metrics configurations](#).

When enabled, request metrics are reported for all object operations. By default, these 1-minute metrics are available at the Amazon S3 bucket level. You can also define a filter for the metrics using a shared prefix, object tag, or access point:

- **Access point** – Access points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. With the access point filter, you can gain insights into your access point usage. For more information about access points, see [Monitoring and logging access points](#).
- **Prefix** – Although the Amazon S3 data model is a flat structure, you can use prefixes to infer a hierarchy. A prefix is similar to a directory name that enables you to group similar objects

together in a bucket. The S3 console supports prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see [Organizing objects using prefixes](#).

- **Tags** – Tags are key-value name pairs that you can add to objects. Tags help you find and organize objects easily. You can also use tags as a filter for metrics configurations so that only objects with those tags are included in the metrics configuration. For more information about object tags, see [Categorizing your storage using tags](#).

To align these metrics to specific business applications, workflows, or internal organizations, you can filter on a shared prefix, object tag, or access point.

Replication metrics

Monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination AWS Region, and the total number of operations that failed replication. Replication rules that have S3 Replication Time Control (S3 RTC) or S3 Replication metrics enabled will publish replication metrics.

For more information, see [Monitoring replication with metrics, event notifications, and statuses](#) or [Meeting compliance requirements with S3 Replication Time Control](#).

Amazon S3 Storage Lens metrics

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). S3 Storage Lens metrics are available in the AWS/S3/Storage-Lens namespace. The CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to *advanced metrics and recommendations*. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

All CloudWatch statistics are retained for a period of 15 months so that you can access historical information and gain a better perspective on how your web application or service is performing.

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. You may need some additional configurations to your CloudWatch alarms, depending on your use cases. For example, you can use metric math expression to create an alarm. For more information, see [Use CloudWatch metrics](#), [Use metric math](#), [Using Amazon CloudWatch alarms](#), and [Create a CloudWatch alarm based on a metric math expression](#) in the *Amazon CloudWatch User Guide*.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information, see the following topics.

Amazon S3 daily storage metrics for buckets in CloudWatch

The AWS/S3 namespace includes the following daily storage metrics for buckets.

Metric	Description
BucketSizeBytes	<p>The amount of data in bytes that is stored in a bucket in the following storage classes:</p> <ul style="list-style-type: none">• Reduced Redundancy Storage (RRS) (REDUCED_REDUNDANCY)• S3 Express One Zone (EXPRESS_ONEZONE)• S3 Glacier Deep Archive (DEEP_ARCHIVE)• S3 Glacier Flexible Retrieval (GLACIER)• S3 Glacier Instant Retrieval (GLACIER_IR)• S3 Intelligent-Tiering (INTELLIGENT_TIERING)• S3 One Zone-Infrequent Access (ONEZONE_IA)• S3 Standard (STANDARD)

Metric	Description
	<ul style="list-style-type: none">• S3 Standard-Infrequent Access (STANDARD_IA) <p>This value is calculated by summing the size of all objects and metadata (such as bucket names) in the bucket (both current and noncurrent objects), including the size of all parts for all incomplete multipart uploads to the bucket.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p> Note</p><p>The S3 Express One Zone storage class is available only for directory buckets.</p></div> <p>Valid storage-type filters (see the <code>StorageType</code> dimension):</p> <ul style="list-style-type: none">• Reduced Redundancy Storage (RRS): <code>ReducedRedundancyStorage</code>• S3 Express One Zone: <code>ExpressOneZoneStorage</code>• S3 Glacier Deep Archive: <code>DeepArchiveObjectOverhead</code> , <code>DeepArchiveS3ObjectOverhead</code> , <code>DeepArchiveStagingStorage</code> , <code>DeepArchiveStorage</code>• S3 Glacier Flexible Retrieval: <code>GlacierObjectOverhead</code> , <code>GlacierS3ObjectOverhead</code> , <code>GlacierStagingStorage</code> , <code>GlacierStorage</code>• S3 Glacier Instant Retrieval: <code>GlacierInstantRetrievalStorage</code> , <code>GlacierIRSizeOverhead</code>• S3 Intelligent-Tiering: <code>IntelligentTieringAAStorage</code> , <code>IntelligentTieringAIAStrage</code> , <code>IntelligentTieringDAAStorage</code> , <code>IntelligentTieringFAStrage</code> , <code>IntelligentTieringIAStorage</code>• S3 One Zone-Infrequent Access: <code>OneZoneIASizeOverhead</code> , <code>OneZoneIAStorage</code>• S3 Standard: <code>StandardStorage</code>

Metric	Description
	<ul style="list-style-type: none">S3 Standard-Infrequent Access: StandardIAObjectOverhead , StandardIASizeOverhead , StandardIAStorage <p>Units: Bytes</p> <p>Valid statistics: Average</p> <p>For more information about the StorageType dimensions, see the section called "Amazon S3 dimensions in CloudWatch".</p>
NumberOfObjects	<p>The total number of objects stored in a general purpose bucket for all storage classes. This value is calculated by counting all objects in the bucket, which includes current and noncurrent objects, delete markers, and the total number of parts for all incomplete multipart uploads to the bucket. For directory buckets with objects in the S3 Express One Zone storage class, this value is calculated by counting all objects in the bucket, but it doesn't include incomplete multiple uploads to the bucket.</p> <p>Valid storage type filters: AllStorageTypes (see the StorageType dimension)</p> <p>Units: Count</p> <p>Valid statistics: Average</p>

Amazon S3 request metrics in CloudWatch

The AWS/S3 namespace includes the following request metrics. These metrics include non-billable requests (in the case of GET requests from CopyObject and Replication).

 **Note**

Amazon S3 request metrics in CloudWatch aren't supported for directory buckets.

Metric	Description
AllRequests	<p>The total number of HTTP requests made to an Amazon S3 bucket, regardless of type. If you're using a metrics configuration with a filter, then this metric returns only the HTTP requests that meet the filter's requirements.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
GetRequests	<p>The number of HTTP GET requests made for objects in an Amazon S3 bucket. This doesn't include list operations. This metric is incremented for the source of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
<p>Note</p> <p>Paginated list-oriented requests, such as ListMultipartUploads, ListParts, ListObjectVersions, and others, are not included in this metric.</p>	
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket. This metric is incremented for the destination of each <code>CopyObject</code> request.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket. This metric also includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p>

Metric	Description
	Valid statistics: Sum
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
	<p> Note</p> <p>DeleteObjects and SelectObjectContent requests are not included in this metric.</p>
SelectRequests	<p>The number of Amazon S3 SelectObjectContent requests made for objects in an Amazon S3 bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
SelectBytesScanned	<p>The number of bytes of data scanned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
SelectBytesReturned	<p>The number of bytes of data returned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
ListRequests	<p>The number of HTTP requests that list the contents of a bucket.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
BytesUploaded	<p>The number of bytes uploaded for requests made to an Amazon S3 bucket, where the request includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
4xxErrors	<p>The number of HTTP 4xx client error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket to when the response starts to be returned.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Amazon S3 bucket. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>

S3 Replication metrics in CloudWatch

You can monitor the progress of replication with S3 Replication metrics by tracking bytes pending, operations pending, and replication latency. For more information, see [Monitoring progress with replication metrics](#).

 **Note**

You can enable alarms for your replication metrics in Amazon CloudWatch. When you set up alarms for your replication metrics, set the **Missing data treatment** field to **Treat missing data as ignore (maintain the alarm state)**.

Metric	Description
Replicati onLatency	The maximum number of seconds by which the replication destination AWS Region is behind the source AWS Region for a given replication rule. Units: Seconds Valid statistics: Max
BytesPend ingReplicatio n	The total number of bytes of objects pending replication for a given replication rule. Units: Bytes Valid statistics: Max
Operation sPendingR eplication	The number of operations pending replication for a given replication rule. Units: Count Valid statistics: Max
Operation sFailedRe plication	The number of operations that failed to replicate for a given replication rule.

Metric	Description
	Units: Count Valid statistics: Sum (total number of failed operations), Average (failure rate), Sample Count (total number of replication operations)

S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace in CloudWatch. The CloudWatch publishing option is available for S3 Storage Lens dashboards that have been upgraded to advanced metrics and recommendations.

For a list of S3 Storage Lens metrics that are published to CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#). For a complete list of dimensions, see [Dimensions](#).

S3 Object Lambda request metrics in CloudWatch

S3 Object Lambda includes the following request metrics.

Metric	Description
AllRequests	The total number of HTTP requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
GetRequests	The number of HTTP GET requests made for objects by using an Object Lambda Access Point. This metric does not include list operations. Units: Count Valid statistics: Sum
BytesUploaded	The number of bytes uploaded to an Amazon S3 bucket by using an Object Lambda Access Point, where the request includes a body.

Metric	Description
	<p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>
PostRequests	<p>The number of HTTP POST requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
PutRequests	<p>The number of HTTP PUT requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
DeleteRequests	<p>The number of HTTP DELETE requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. This metric includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
BytesDownloaded	<p>The number of bytes downloaded for requests made to an Amazon S3 bucket by using an Object Lambda Access Point, where the response includes a body.</p> <p>Units: Bytes</p> <p>Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9</p>

Metric	Description
FirstByteLatency	<p>The per-request time from the complete request being received by an Amazon S3 bucket through an Object Lambda Access Point to when the response starts to be returned. This metric is dependent on the AWS Lambda function's running time to transform the object before the function returns the bytes to the Object Lambda Access Point.</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
TotalRequestLatency	<p>The elapsed per-request time from the first byte received to the last byte sent to an Object Lambda Access Point. This metric includes the time taken to receive the request body and send the response body, which is not included in FirstByteLatency .</p> <p>Units: Milliseconds</p> <p>Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100</p>
HeadRequests	<p>The number of HTTP HEAD requests made to an Amazon S3 bucket by using an Object Lambda Access Point.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
ListRequests	<p>The number of HTTP GET requests that list the contents of an Amazon S3 bucket. This metric includes both ListObjects and ListObjectsV2 operations.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
4xxErrors	<p>The number of HTTP 4xx client error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
5xxErrors	<p>The number of HTTP 5xx server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period.</p> <p>Units: Count</p> <p>Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count</p>
ProxiedRequests	<p>The number of HTTP requests to an Object Lambda Access Point that return the standard Amazon S3 API response. (Such requests do not have a Lambda function configured.)</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>
InvokedLambda	<p>The number of HTTP requests to an S3 object where a Lambda function was invoked.</p> <p>Units: Count</p> <p>Valid statistics: Sum</p>

Metric	Description
LambdaResponseRequests	The number of <code>WriteGetObjectResponse</code> requests made by the Lambda function. This metric applies only to <code>GetObject</code> requests.
LambdaResponse4xx	The number of HTTP 4xx client errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>4xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.
LambdaResponse5xx	The number of HTTP 5xx server errors that occur when calling <code>WriteGetObjectResponse</code> from a Lambda function. This metric provides the same information as <code>5xxErrors</code> , but only for <code>WriteGetObjectResponse</code> calls.

Amazon S3 dimensions in CloudWatch

The following dimensions are used to filter Amazon S3 metrics.

Dimension	Description
BucketName	This dimension filters the data that you request for the identified bucket only.
StorageType	This dimension filters the data that you have stored in a bucket by the following types of storage: <ul style="list-style-type: none"> • <code>DeepArchiveObjectOverhead</code> – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive rates for this additional storage. • <code>DeepArchiveS3ObjectOverhead</code> – For each object archived to S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.

Dimension	Description
	<ul style="list-style-type: none">• DeepArchiveStagingStorage – The number of bytes used for parts of multipart upload objects before the CompleteMultipartUpload request is completed on objects in the S3 Glacier Deep Archive storage class.• DeepArchiveStorage – The number of bytes used for objects in the S3 Glacier Deep Archive storage class.• ExpressOneZoneStorage – The number of bytes used for objects in the S3 Express One Zone storage class.• GlacierInstantRetrievalStorage – The number of bytes used for objects in the S3 Glacier Instant Retrieval storage class.• GlacierIRSizeOverhead – The number of bytes used for objects smaller than 128 KB in the S3 Glacier Instant Retrieval storage class.• GlacierObjectOverhead – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage.• GlacierS30bjectOverhead – For each object archived to S3 Glacier Flexible Retrieval, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.• GlacierStagingStorage – The number of bytes used for parts of multipart upload objects before the CompleteMultipartUpload request is completed on objects in the S3 Glacier Flexible Retrieval storage class.• GlacierStorage – The number of bytes used for objects in the S3 Glacier Flexible Retrieval storage class.• IntAA0bjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify

Dimension	Description
	<p>and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage.</p> <ul style="list-style-type: none"> • IntAAS3ObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Archive Access tier, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • IntDAAObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Deep Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive storage rates for this additional storage. • IntDAAS3ObjectOverhead – For each object in the INTELLIGENT_TIERING storage class in the Deep Archive Access tier, Amazon S3 adds 8 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Standard rates for this additional storage. • IntelligentTieringAAStorage – The number of bytes used for objects in the Archive Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringAIStorage – The number of bytes used for objects in the Archive Instant Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringDAAStorage – The number of bytes used for objects in the Deep Archive Access tier of the INTELLIGENT_TIERING storage class. • IntelligentTieringFAStorage – The number of bytes used for objects in the Frequent Access tier of the INTELLIGENT_TIERING storage class.

Dimension	Description
	<ul style="list-style-type: none"> • IntelligentTieringIAStorage – The number of bytes used for objects in the Infrequent Access tier of the INTELLIGENT_TIERING storage class. • OneZoneIASizeOverhead – The number of bytes used for objects smaller than 128 KB in the ONEZONE_IA storage class. • OneZoneIAStorage – The number of bytes used for objects in the S3 One Zone-Infrequent Access (ONEZONE_IA) storage class. • ReducedRedundancyStorage – The number of bytes used for objects in the Reduced Redundancy Storage (RRS) class. • StandardIASizeOverhead – The number of bytes used for objects smaller than 128 KB in the STANDARD_IA storage class. • StandardIAStorage – The number of bytes used for objects in the S3 Standard-Infrequent Access (STANDARD_IA) storage class. • StandardStorage – The number of bytes used for objects in the STANDARD storage class.
FilterId	<p>This dimension filters metrics configurations that you specify for the request metrics on a bucket. When you create a metrics configuration, you specify a filter ID (for example, a prefix, a tag, or an access point). For more information, see Creating a metrics configuration.</p>

S3 Replication dimensions in CloudWatch

The following dimensions are used to filter S3 Replication metrics.

Dimension	Description
SourceBucket	The name of the bucket objects are replicated from.
DestinationBucket	The name of the bucket objects are replicated to.
RuleId	A unique identifier for the rule that triggered this replication metric to update.

S3 Storage Lens dimensions in CloudWatch

For a list of dimensions that are used to filter S3 Storage Lens metrics in CloudWatch, see [Dimensions](#).

S3 Object Lambda request dimensions in CloudWatch

The following dimensions are used to filter data from an Object Lambda Access Point.

Dimension	Description
AccessPointName	The name of the access point of which requests are being made.
DataSourceARN	The source the Object Lambda Access Point is retrieving the data from. If the request invokes a Lambda function this refers to the Lambda Amazon Resource Name (ARN). Otherwise this refers to the access point ARN.

Amazon S3 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon S3 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see [AWS usage metrics in the Amazon CloudWatch User Guide](#).

Amazon S3 publishes the following metrics in the AWS/Usage namespace.

Metric	Description
ResourceCount	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric.

The following dimensions are used to refine the usage metrics that are published by Amazon S3.

Dimension	Description
Service	The name of the AWS service containing the resource. For Amazon S3 usage metrics, the value for this dimension is S3.
Type	The type of entity that is being reported. Currently, the only valid value for Amazon S3 usage metrics is Resource.
Resource	The type of resource that is running. Currently, the only valid value for Amazon S3 usage metrics is GeneralPurposeBuckets , which returns the number of general purpose buckets in an AWS account. General purpose buckets allow objects that are stored across all storage classes, except S3 Express One Zone.

Accessing CloudWatch metrics

You can use the following procedures to view the storage metrics for Amazon S3. To get the Amazon S3 metrics involved, you must set a start and end timestamp. For metrics for any given 24-hour period, set the time period to 86400 seconds, the number of seconds in a day. Also, remember to set the BucketName and StorageType dimensions.

Using the AWS CLI

For example, if you want to use the AWS CLI to get the average of a specific bucket's size in bytes, you could use the following command:

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --namespace AWS/S3  
--start-time 2016-10-19T00:00:00Z --end-time 2016-10-20T00:00:00Z --statistics Average
```

```
--unit Bytes --region us-west-2 --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
Name=StorageType,Value=StandardStorage --period 86400 --output json
```

This example produces the following output.

```
{
  "Datapoints": [
    {
      "Timestamp": "2016-10-19T00:00:00Z",
      "Average": 1025328.0,
      "Unit": "Bytes"
    }
  ],
  "Label": "BucketSizeBytes"
}
```

Using the S3 console

To view metrics by using the Amazon CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the left navigation pane, choose **Metrics**.
3. Choose the **S3** namespace.
4. (Optional) To view a metric, enter the metric name in the search box.
5. (Optional) To filter by the **StorageType** dimension, enter the name of the storage class in the search box.

To view a list of valid metrics stored for your AWS account by using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/S3"
```

For more information about the permissions required to access CloudWatch dashboards, see [Amazon CloudWatch dashboard permissions](#) in the *Amazon CloudWatch User Guide*.

CloudWatch metrics configurations

With Amazon CloudWatch request metrics for Amazon S3, you can receive 1-minute CloudWatch metrics, set CloudWatch alarms, and access CloudWatch dashboards to view near-real-time operations and performance of your Amazon S3 storage. For applications that depend on cloud storage, these metrics let you quickly identify and act on operational issues. When enabled, these 1-minute metrics are available at the Amazon S3 bucket-level, by default.

If you want to get the CloudWatch request metrics for the objects in a bucket, you must create a metrics configuration for the bucket. For more information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

You can also use a shared prefix, object tags, or an access point to define a filter for the metrics collected. This method of defining a filter allows you to align metrics filters to specific business applications, workflows, or internal organizations. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#). For more information about the CloudWatch metrics that are available and the differences between storage and request metrics, see [Monitoring metrics with Amazon CloudWatch](#).

Keep the following in mind when using metrics configurations:

- You can have a maximum of 1,000 metrics configurations per bucket.
- You can choose which objects in a bucket to include in metrics configurations by using filters. You can filter on a shared prefix, object tag, or access point to align metrics filters to specific business applications, workflows, or internal organizations. To request metrics for the entire bucket, create a metrics configuration without a filter.
- Metrics configurations are necessary only to enable request metrics. Bucket-level daily storage metrics are always turned on, and are provided at no additional cost. Currently, it's not possible to get daily storage metrics for a filtered subset of objects.
- Each metrics configuration enables the full set of [available request metrics](#). Operation-specific metrics (such as PostRequests) are reported only if there are requests of that type for your bucket or your filter.
- Request metrics are reported for object-level operations. They are also reported for operations that list bucket contents, like [GET Bucket \(List Objects\)](#), [GET Bucket Object Versions](#), and [List Multipart Uploads](#), but they are not reported for other operations on buckets.
- Request metrics support filtering by prefix, object tags, or access point, but storage metrics do not.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the [Billing & Cost Management Dashboard](#) might include one or more access requests that do not appear in the bucket metrics.

For more information about working with CloudWatch metrics in Amazon S3, see the following topics.

Topics

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)
- [Deleting a metrics filter](#)

Creating a CloudWatch metrics configuration for all the objects in your bucket

When you configure request metrics, you can create a CloudWatch metrics configuration for all the objects in your bucket, or you can filter by prefix, object tag, or access point. The procedures in this topic show you how to create a configuration for all the objects in your bucket. To create a configuration that filters by object tag, prefix, or access point, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication metrics](#) provide detailed metrics for the replication rules in your replication configuration. With

replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

You can add metrics configurations to a bucket using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

Names can only contain letters, numbers, periods, dashes, and underscores. We recommend using the name `EntireBucket` for a filter that applies to all objects.

9. Under **Filter scope**, choose **This filter applies to all objects in the bucket**.

You can also define a filter so that the metrics are only collected and reported on a subset of objects in the bucket. For more information, see [Creating a metrics configuration that filters by prefix, object tag, or access point](#).

10. Choose **Save changes**.
11. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

After about 15 minutes, CloudWatch begins tracking these request metrics. You can see them on the **Request metrics** tab. You can see graphs for the metrics on the Amazon S3 or CloudWatch console. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. Run the following command to add a metrics configuration.

```
aws s3api put-bucket-metrics-configuration --endpoint https://s3.us-west-2.amazonaws.com --bucket bucket-name --id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'}'
```

Creating a metrics configuration that filters by prefix, object tag, or access point

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. [S3 Replication metrics](#) provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see [Monitoring metrics with Amazon CloudWatch](#).

When you configure CloudWatch metrics, you can create a filter for all the objects in your bucket, or you can filter the configuration into groups of related objects within a single bucket. You can filter objects in a bucket for inclusion in a metrics configuration based on one or more of the following filter types:

- **Object key name prefix** – Although the Amazon S3 data model is a flat structure, you can infer a hierarchy by using a prefix. The Amazon S3 console supports these prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see [Organizing objects using prefixes](#).
- **Tag** – You can add tags, which are key-value name pairs, to objects. Tags help you find and organize objects easily. You can also use tags as filters for metrics configurations. For more information about object tags, see [Categorizing your storage using tags](#).
- **Access point** – S3 Access Points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. When you create an access point filter, Amazon S3 includes requests to the access point that you specify in the metrics configuration. For more information, see [Monitoring and logging access points](#).

 **Note**

When you create a metrics configuration that filters by access point, you must use the access point Amazon Resource Name (ARN), not the access point alias. Make sure that you use the ARN for the access point itself, not the ARN for a specific object. For more information about access point ARNs, see [Using Amazon S3 access points](#).

If you specify a filter, only requests that operate on single objects can match the filter and be included in the reported metrics. Requests like [DeleteObjects](#) and [ListObjects](#) requests don't return any metrics for configurations with filters.

To request more complex filtering, choose two or more elements. Only objects that have all of those elements are included in the metrics configuration. If you don't set filters, all of the objects in the bucket are included in the metrics configuration.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**

3. In the buckets list, choose the name of the bucket that contains the objects that you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

Names can contain only letters, numbers, periods, dashes, and underscores.
9. Under **Filter scope**, choose **Limit the scope of this filter using a prefix, object tags, and an S3 Access Point, or a combination of all three**.
10. Under **Filter type**, choose at least one filter type: **Prefix**, **Object tags**, or **Access Point**.
11. To define a prefix filter and limit the scope of the filter to a single path, in the **Prefix** box, enter a prefix.
12. To define an object tags filter, under **Object tags**, choose **Add tag**, and then enter a tag **Key** and **Value**.
13. To define an access point filter, in the **S3 Access Point** field, enter the access point ARN, or choose **Browse S3** to navigate to the access point.

⚠ Important

You cannot enter an access point alias. You must enter the ARN for the access point itself, not the ARN for a specific object.

14. Choose **Save changes**.

Amazon S3 creates a filter that uses the prefix, tags, or access point that you specified.

15. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

You have now created a filter that limits the request metrics scope by prefix, object tags, or access point. About 15 minutes after CloudWatch begins tracking these request metrics, you can see charts for the metrics on both the Amazon S3 and CloudWatch consoles. Request metrics are billed at the standard CloudWatch rate. For more information, see [Amazon CloudWatch pricing](#).

You can also configure request metrics at the bucket level. For information, see [Creating a CloudWatch metrics configuration for all the objects in your bucket](#).

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. To add a metrics configuration, run one of the following commands:

Example : To filter by prefix

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Prefix":"'prefix1'"}' '
```

Example : To filter by tags

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"Tag": {"Key": "string", "Value": "string"} }' '
```

Example : To filter by access point

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --  
id metrics-config-id --metrics-configuration '{"Id":"'metrics-config-id'", "Filter":  
{"AccessPointArn":":arn:aws:s3:Region:account-id:accesspoint/access-point-name"} }' '
```

Example : To filter by prefix, tags, and access point

```
aws s3api put-bucket-metrics-configuration --endpoint https://  
s3.Region.amazonaws.com --bucket amzn-s3-demo-bucket --id metrics-config-id --  
metrics-configuration '  
{  
    "Id": "metrics-config-id",  
    "Filter": {  
        "And": {  
            "Prefix": "string",
```

```
"Tags": [  
    {  
        "Key": "string",  
        "Value": "string"  
    }  
,  
    "AccessPointArn": "arn:aws:s3:Region:account-id:accesspoint/access-point-name"  
}  
}  
}'
```

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Deleting a metrics filter

You can delete an Amazon CloudWatch request metrics filter if you no longer need it. When you delete a filter, you are no longer charged for request metrics that use that *specific filter*. However, you will continue to be charged for any other filter configurations that exist.

When you delete a filter, you can no longer use the filter for request metrics. Deleting a filter cannot be undone.

For information about creating a request metrics filter, see the following topics:

- [Creating a CloudWatch metrics configuration for all the objects in your bucket](#)
- [Creating a metrics configuration that filters by prefix, object tag, or access point](#)

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket you want to delete a request metrics filter for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Manage filters**.
8. Choose your filter.

 **Important**

Deleting a filter cannot be undone.

9. Choose **Delete**.

Amazon S3 deletes your filter.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- [PUT Bucket Metric Configuration](#)
- [GET Bucket Metric Configuration](#)
- [List Bucket Metric Configuration](#)
- [DELETE Bucket Metric Configuration](#)

Amazon S3 Event Notifications

You can use the Amazon S3 Event Notifications feature to receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that

identifies the events that you want Amazon S3 to publish. Make sure that it also identifies the destinations where you want Amazon S3 to send the notifications. You store this configuration in the *notification* subresource that's associated with a bucket. For more information, see [Bucket configuration options](#). Amazon S3 provides an API for you to manage this subresource.

 **Important**

Amazon S3 event notifications are designed to be delivered at least once. Typically, event notifications are delivered in seconds but can sometimes take a minute or longer.

Overview of Amazon S3 Event Notifications

Currently, Amazon S3 can publish notifications for the following events:

- New object created events
- Object removal events
- Restore object events
- Reduced Redundancy Storage (RRS) object lost events
- Replication events
- S3 Lifecycle expiration events
- S3 Lifecycle transition events
- S3 Intelligent-Tiering automatic archival events
- Object tagging events
- Object ACL PUT events

For full descriptions of all the supported event types, see [Supported event types for SQS, SNS, and Lambda](#).

Amazon S3 can send event notification messages to the following destinations. You specify the Amazon Resource Name (ARN) value of these destinations in the notification configuration.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda function
- Amazon EventBridge

For more information, see [Supported event destinations](#).

 **Note**

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

 **Warning**

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

For more information about the number of event notification configurations that you can create per bucket, see [Amazon S3 service quotas](#) in *AWS General Reference*.

For more information about event notifications, see the following sections.

Topics

- [Event notification types and destinations](#)
- [Using Amazon SQS, Amazon SNS, and Lambda](#)
- [Using EventBridge](#)

Event notification types and destinations

Amazon S3 supports several event notification types and destinations where the notifications can be published. You can specify the event type and destination when configuring your event notifications. Only one destination can be specified for each event notification. Amazon S3 event notifications send one event entry for each notification message.

Topics

- [Supported event destinations](#)
- [Supported event types for SQS, SNS, and Lambda](#)
- [Supported event types for Amazon EventBridge](#)
- [Event ordering and duplicate events](#)

Supported event destinations

Amazon S3 can send event notification messages to the following destinations.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda
- Amazon EventBridge

However, only one destination type can be specified for each event notification.

 **Note**

You must grant Amazon S3 permissions to post messages to an Amazon SNS topic or an Amazon SQS queue. You must also grant Amazon S3 permission to invoke an AWS Lambda function on your behalf. For instructions on how to grant these permissions, see [Granting permissions to publish event notification messages to a destination](#).

Amazon SNS topic

Amazon SNS is a flexible, fully managed push messaging service. You can use this service to push messages to mobile devices or distributed services. With SNS, you can publish a message once, and deliver it one or more times. Currently, Standard SNS is only allowed as an S3 event notification destination, whereas SNS FIFO is not allowed.

Amazon SNS both coordinates and manages sending and delivering messages to subscribing endpoints or clients. You can use the Amazon SNS console to create an Amazon SNS topic that your notifications can be sent to.

The topic must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SNS topic, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide* and the [Amazon SNS FAQ](#).

Before you can use the Amazon SNS topic that you created as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SNS topic
- A valid Amazon SNS topic subscription. With it, topic subscribers are notified when a message is published to your Amazon SNS topic.

Amazon SQS queue

Amazon SQS offers reliable and scalable hosted queues for storing messages as they travel between computers. You can use Amazon SQS to transmit any volume of data without requiring other services to be always available. You can use the Amazon SQS console to create an Amazon SQS queue that your notifications can be sent to.

The Amazon SQS queue must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SQS queue, see [What is Amazon Simple Queue Service](#) and [Getting started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.

Before you can use the Amazon SQS queue as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SQS queue

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Lambda function

You can use AWS Lambda to extend other AWS services with custom logic, or create your own backend that operates at AWS scale, performance, and security. With Lambda, you can create

discrete, event-driven applications that run only when needed. You can also use it to scale these applications automatically from a few requests a day to thousands a second.

Lambda can run custom code in response to Amazon S3 bucket events. You upload your custom code to Lambda and create what's called a Lambda function. When Amazon S3 detects an event of a specific type, it can publish the event to AWS Lambda and invoke your function in Lambda. In response, Lambda runs your function. One event type it might detect, for example, is an object created event.

You can use the AWS Lambda console to create a Lambda function that uses the AWS infrastructure to run the code on your behalf. The Lambda function must be in the same Region as your S3 bucket. You must also have the name or the ARN of a Lambda function to set up the Lambda function as an event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

For more information and an example of using Amazon S3 notifications with AWS Lambda, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Amazon EventBridge

Amazon EventBridge is a serverless event bus, which receives events from AWS services. You can set up rules to match events and deliver them to targets, such as an AWS service or an HTTP endpoint. For more information, see [What is EventBridge](#) in the *Amazon EventBridge User Guide*.

Unlike other destinations, you can either enable or disable events to be delivered to EventBridge for a bucket. If you enable delivery, all events are sent to EventBridge. Moreover, you can use EventBridge rules to route events to additional targets.

Supported event types for SQS, SNS, and Lambda

Amazon S3 can publish events of the following types. You specify these event types in the notification configuration.

Event types	Description
s3:TestEvent	<p>When a notification is enabled, Amazon S3 publishes a test notification. This is to ensure that the topic exists and that the bucket owner has permission to publish the specified topic.</p> <p>If enabling the notification fails, you don't receive a test notification.</p>
s3:ObjectCreated:*	<p>Amazon S3 API operations such as PUT, POST, and COPY can create an object. With these event types, you can enable notifications when an object is created using a specific API operation. Alternatively, you can use the s3:ObjectCreated: * event type to request notification regardless of the API that was used to create an object.</p> <p>s3:ObjectCreated:CompleteMultipartUpload includes objects that are created using UploadPartCopy for Copy operations.</p>
s3:ObjectRemoved:*	<p>By using the ObjectRemoved event types, you can enable notification when an object or a batch of objects is removed from a bucket.</p> <p>You can request notification when an object is deleted or a versioned object is permanently deleted by using the s3:ObjectRemoved:Delete event type. Alternatively, you can request notification when a delete marker is created for a versioned object using s3:ObjectRemoved:DeleteMarkerCreated. For instructions on how to delete versioned objects, see Deleting object versions from a versioning-enabled bucket. You can also use a wildcard s3:ObjectRemoved: * to request notification anytime an object is deleted.</p>

Event types	Description
	These event notifications don't alert you for automatic deletes from lifecycle configurations or from failed operations.
<code>s3:ObjectRestore:*</code> <code>s3:ObjectRestore:Post</code> <code>s3:ObjectRestore:Completed</code> <code>s3:ObjectRestore:Delete</code>	<p>By using the <code>ObjectRestore</code> event types, you can receive notifications for event initiation and completion when restoring objects from the S3 Glacier Flexible Retrieval storage class, S3 Glacier Deep Archive storage class, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier. You can also receive notifications for when the restored copy of an object expires.</p> <p>The <code>s3:ObjectRestore:Post</code> event type notifies you of object restoration initiation. The <code>s3:ObjectRestore:Completed</code> event type notifies you of restoration completion. The <code>s3:ObjectRestore:Delete</code> event type notifies you when the temporary copy of a restored object expires.</p>
<code>s3:ReducedRedundancyLostObject</code>	You receive this notification event when Amazon S3 detects that an object of the RRS storage class is lost.

Event types	Description
<p>s3:Replication:*</p> <p>s3:Replication:OperationFailedReplication</p> <p>s3:Replication:OperationMissedThreshold</p> <p>s3:Replication:OperationReplicatedAfterThreshold</p> <p>s3:Replication:OperationNotTracked</p>	<p>By using the Replication event types, you can receive notifications for replication configurations that have S3 Replication metrics or S3 Replication Time Control (S3 RTC) enabled. You can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For information about replication metrics, see Monitoring replication with metrics, event notifications, and statuses.</p> <ul style="list-style-type: none">The s3:Replication:OperationFailedReplication event type notifies you when an object that was eligible for replication failed to replicate.The s3:Replication:OperationMissedThreshold event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.The s3:Replication:OperationReplicatedAfterThreshold event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.The s3:Replication:OperationNotTracked event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

Event types	Description
<p>s3:LifecycleExpiration:*</p> <p>s3:LifecycleExpiration:Delete</p> <p>s3:LifecycleExpiration:DeleteMarkerCreated</p>	<p>By using the LifecycleExpiration event types, you can receive a notification when Amazon S3 deletes an object based on your S3 Lifecycle configuration.</p> <p>The s3:LifecycleExpiration:Delete event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration.</p> <p>The s3:LifecycleExpiration:DeleteMarkerCreated event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted.</p>
<p>s3:LifecycleTransition</p>	<p>You receive this notification event when an object is transitioned to another Amazon S3 storage class by an S3 Lifecycle configuration.</p>
<p>s3:IntelligentTiering</p>	<p>You receive this notification event when an object within the S3 Intelligent-Tiering storage class moved to the Archive Access tier or Deep Archive Access tier.</p>
<p>s3:ObjectTagging:*</p> <p>s3:ObjectTagging:Put</p> <p>s3:ObjectTagging:Delete</p>	<p>By using the ObjectTagging event types, you can enable notification when an object tag is added or deleted from an object.</p> <p>The s3:ObjectTagging:Put event type notifies you when a tag is PUT on an object or an existing tag is updated. The s3:ObjectTagging:Delete event type notifies you when a tag is removed from an object.</p>
<p>s3:ObjectAcl:Put</p>	<p>You receive this notification event when an ACL is PUT on an object or when an existing ACL is changed. An event is not generated when a request results in no change to an object's ACL.</p>

Supported event types for Amazon EventBridge

For a list of event types Amazon S3 will send to Amazon EventBridge, see [Using EventBridge](#).

Event ordering and duplicate events

Amazon S3 Event Notifications is designed to deliver notifications at least once, but they aren't guaranteed to arrive in the same order that the events occurred. On rare occasions, Amazon S3's retry mechanism might cause duplicate S3 Event Notifications for the same object event. For more about handling duplicate or out of order events, see [Manage event ordering and duplicate events with Amazon S3 Event Notifications](#) on the [AWS Storage Blog](#).

Using Amazon SQS, Amazon SNS, and Lambda

Enabling notifications is a bucket-level operation. You store notification configuration information in the *notification* subresource that's associated with a bucket. After you create or change the bucket notification configuration, it usually takes about five minutes for the changes to take effect. When the notification is first enabled, an s3:TestEvent occurs. You can use any of the following methods to manage notification configuration:

- **Using the Amazon S3 console** — You can use the console UI to set a notification configuration on a bucket without having to write any code. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).
- **Programmatically using the AWS SDKs** — Internally, both the console and the SDKs call the Amazon S3 REST API to manage *notification* subresources that are associated with the bucket. For examples of notification configurations that use AWS SDK, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

 **Note**

You can also make the Amazon S3 REST API calls directly from your code. However, this can be cumbersome because to do so you must write code to authenticate your requests.

Regardless of the method that you use, Amazon S3 stores the notification configuration as XML in the *notification* subresource that's associated with a bucket. For information about bucket subresources, see [Bucket configuration options](#).

Note

If you have multiple failed event notifications due to deleted destinations you may receive the **Unable to validate the following destination configurations** when trying to delete them. You can resolve this in the S3 console by deleting all the failed notifications at the same time.

Topics

- [Granting permissions to publish event notification messages to a destination](#)
- [Enabling and configuring event notifications using the Amazon S3 console](#)
- [Configuring event notifications programmatically](#)
- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#)
- [Configuring event notifications using object key name filtering](#)
- [Event message structure](#)

Granting permissions to publish event notification messages to a destination

You must grant the Amazon S3 principal the necessary permissions to call the relevant API to publish messages to an SNS topic, an SQS queue, or a Lambda function. This is so that Amazon S3 can publish event notification messages to a destination.

To troubleshoot publishing event notification messages to a destination, see [Troubleshoot to publish Amazon S3 event notifications to an Amazon Simple Notification Service topic](#).

Topics

- [Granting permissions to invoke an AWS Lambda function](#)
- [Granting permissions to publish messages to an SNS topic or an SQS queue](#)

Granting permissions to invoke an AWS Lambda function

Amazon S3 publishes event messages to AWS Lambda by invoking a Lambda function and providing the event message as an argument.

When you use the Amazon S3 console to configure event notifications on an Amazon S3 bucket for a Lambda function, the console sets up the necessary permissions on the Lambda function. This is

so that Amazon S3 has permissions to invoke the function from the bucket. For more information, see [Enabling and configuring event notifications using the Amazon S3 console](#).

You can also grant Amazon S3 permissions from AWS Lambda to invoke your Lambda function. For more information, see [Tutorial: Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Granting permissions to publish messages to an SNS topic or an SQS queue

To grant Amazon S3 permissions to publish messages to the SNS topic or SQS queue, attach an AWS Identity and Access Management (IAM) policy to the destination SNS topic or SQS queue.

For an example of how to attach a policy to an SNS topic or an SQS queue, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#). For more information about permissions, see the following topics:

- [Example cases for Amazon SNS access control](#) in the *Amazon Simple Notification Service Developer Guide*
- [Identity and access management in Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*

IAM policy for a destination SNS topic

The following is an example of an AWS Identity and Access Management (IAM) policy that you attach to the destination SNS topic. For instructions on how to use this policy to set up a destination Amazon SNS topic for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "Example SNS topic policy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": [  
                "SNS:Publish"  
            ]  
        }  
    ]  
}
```

```
],
  "Resource": "SNS-topic-ARN",
  "Condition": {
    "ArnLike": {
      "aws:SourceArn": "arn:aws:s3::*:*:amzn-s3-demo-bucket"
    },
    "StringEquals": {
      "aws:SourceAccount": "bucket-owner-account-id"
    }
  }
}
]
```

IAM policy for a destination SQS queue

The following is an example of an IAM policy that you attach to the destination SQS queue. For instructions on how to use this policy to set up a destination Amazon SQS queue for event notifications, see [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

To use this policy, you must update the Amazon SQS queue ARN, bucket name, and bucket owner's AWS account ID.

```
{
  "Version": "2012-10-17",
  "Id": "example-ID",
  "Statement": [
    {
      "Sid": "example-statement-ID",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": [
        "SQS:SendMessage"
      ],
      "Resource": "arn:aws:sqs:Region:account-id:queue-name",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3::*:*:awsexamplebucket1"
        },
        "StringEquals": {
          "aws:SourceAccount": "bucket-owner-account-id"
        }
      }
    }
  ]
}
```

```
        }
    }
}
]
```

For both the Amazon SNS and Amazon SQS IAM policies, you can specify the `StringLike` condition in the policy instead of the `ArnLike` condition.

When `ArnLike` is used, the partition, service, account-id, resource-type, and partial resource-id portions of the ARN must have exact matching to the ARN in the request context. Only the region and resource path allow partial matching.

When `StringLike` is used instead of `ArnLike`, matching ignores the ARN structure and allows partial matching, regardless of the portion that was wildcarded. For more information, see [IAM JSON policy elements](#) in the *IAM User Guide*.

```
"Condition": {
    "StringLike": { "aws:SourceArn": "arn:aws:s3::*:*:amzn-s3-demo-bucket" }
}
```

AWS KMS key policy

If the SQS queue or SNS topics are encrypted with an AWS Key Management Service (AWS KMS) customer managed key, you must grant the Amazon S3 service principal permission to work with the encrypted topics or queue. To grant the Amazon S3 service principal permission, add the following statement to the key policy for the customer managed key.

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ]
        }
    ]
}
```

```
        ],
        "Resource": "*"
    }
]
```

For more information about AWS KMS key policies, see [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

For more information about using server-side encryption with AWS KMS for Amazon SQS and Amazon SNS, see the following:

- [Key management](#) in the *Amazon Simple Notification Service Developer Guide*.
- [Key management](#) in the *Amazon Simple Queue Service Developer Guide*.
- [Encrypting messages published to Amazon SNS with AWS KMS](#) in the *AWS Compute Blog*.

Enabling and configuring event notifications using the Amazon S3 console

You can enable certain Amazon S3 general purpose bucket events to send a notification message to a destination whenever those events occur. This section explains how to use the Amazon S3 console to enable event notifications. For information about how to use event notifications with the AWS SDKs and the Amazon S3 REST APIs, see [Configuring event notifications programmatically](#).

Prerequisites: Before you can enable event notifications for your bucket, you must set up one of the destination types and then configure permissions. For more information, see [Supported event destinations](#) and [Granting permissions to publish event notification messages to a destination](#).

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console](#)

Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

To enable and configure event notifications for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and choose **Create event notification**.
6. In the **General configuration** section, specify descriptive event name for your event notification. Optionally, you can also specify a prefix and a suffix to limit the notifications to objects with keys ending in the specified characters.
 - a. Enter a description for the **Event name**.

If you don't enter a name, a globally unique identifier (GUID) is generated and used for the name.

- b. (Optional) To filter event notifications by prefix, enter a **Prefix**.

For example, you can set up a prefix filter so that you receive notifications only when files are added to a specific folder (for example, `images/`).
- c. (Optional) To filter event notifications by suffix, enter a **Suffix**.

For more information, see [Configuring event notifications using object key name filtering](#).

7. In the **Event types** section, select one or more event types that you want to receive notifications for.

For a list of the different event types, see [Supported event types for SQS, SNS, and Lambda](#).

8. In the **Destination** section, choose the event notification destination.

Note

Before you can publish event notifications, you must grant the Amazon S3 principal the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function, SNS topic, or SQS queue.

- a. Select the destination type: **Lambda Function, SNS Topic, or SQS Queue**.
- b. After you choose your destination type, choose a function, topic, or queue from the list.
- c. Or, if you prefer to specify an Amazon Resource Name (ARN), select **Enter ARN** and enter the ARN.

For more information, see [Supported event destinations](#).

9. Choose **Save changes**, and Amazon S3 sends a test message to the event notification destination.

Configuring event notifications programmatically

By default, notifications aren't enabled for any type of event. Therefore, the *notification* subresource initially stores an empty configuration.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</NotificationConfiguration>
```

To enable notifications for events of specific types, you replace the XML with the appropriate configuration that identifies the event types you want Amazon S3 to publish and the destination where you want the events published. For each destination, you add a corresponding XML configuration.

To publish event messages to an SQS queue

To set an SQS queue as the notification destination for one or more event types, add the `QueueConfiguration`.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>optional-id-string</Id>
    <Queue>sqs-queue-arn</Queue>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </QueueConfiguration>
  ...
</NotificationConfiguration>
```

To publish event messages to an SNS topic

To set an SNS topic as the notification destination for specific event types, add the TopicConfiguration.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Id>optional-id-string</Id>
    <Topic>sns-topic-arn</Topic>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </TopicConfiguration>
  ...
</NotificationConfiguration>
```

To invoke the AWS Lambda function and provide an event message as an argument

To set a Lambda function as the notification destination for specific event types, add the CloudFunctionConfiguration.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>optional-id-string</Id>
    <CloudFunction>cloud-function-arn</CloudFunction>
    <Event>event-type</Event>
    <Event>event-type</Event>
    ...
  </CloudFunctionConfiguration>
  ...
</NotificationConfiguration>
```

To remove all notifications configured on a bucket

To remove all notifications configured on a bucket, save an empty <NotificationConfiguration/> element in the *notification* subresource.

When Amazon S3 detects an event of the specific type, it publishes a message with the event information. For more information, see [Event message structure](#).

For more information about configuring event notifications, see the following topics:

- [Walkthrough: Configuring a bucket for notifications \(SNS topic or SQS queue\)](#).

- [Configuring event notifications using object key name filtering](#)

Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)

You can receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) or Amazon Simple Queue Service (Amazon SQS). In this walkthrough, you add a notification configuration to your bucket using an Amazon SNS topic and an Amazon SQS queue.

Note

Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see [Enabling Amazon EventBridge](#).

Topics

- [Walkthrough summary](#)
- [Step 1: Create an Amazon SQS queue](#)
- [Step 2: Create an Amazon SNS topic](#)
- [Step 3: Add a notification configuration to your bucket](#)
- [Step 4: Test the setup](#)

Walkthrough summary

This walkthrough helps you do the following:

- Publish events of the `s3:ObjectCreated:*` type to an Amazon SQS queue.
- Publish events of the `s3:ReducedRedundancyLostObject` type to an Amazon SNS topic.

For information about notification configuration, see [Using Amazon SQS, Amazon SNS, and Lambda](#).

You can do all these steps using the console, without writing any code. In addition, code examples using AWS SDKs for Java and .NET are also provided to help you add notification configurations programmatically.

The procedure includes the following steps:

1. Create an Amazon SQS queue.

Using the Amazon SQS console, create an SQS queue. You can access any messages Amazon S3 sends to the queue programmatically. But, for this walkthrough, you verify notification messages in the console.

You attach an access policy to the queue to grant Amazon S3 permission to post messages.

2. Create an Amazon SNS topic.

Using the Amazon SNS console, create an SNS topic and subscribe to the topic. That way, any events posted to it are delivered to you. You specify email as the communications protocol. After you create a topic, Amazon SNS sends an email. You use the link in the email to confirm the topic subscription.

You attach an access policy to the topic to grant Amazon S3 permission to post messages.

3. Add notification configuration to a bucket.

Step 1: Create an Amazon SQS queue

Follow the steps to create and subscribe to an Amazon Simple Queue Service (Amazon SQS) queue.

1. Using the Amazon SQS console, create a queue. For instructions, see [Getting Started with Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.
2. Replace the access policy that's attached to the queue with the following policy.
 - a. In the Amazon SQS console, in the **Queues** list, choose the queue name.
 - b. On the **Access policy** tab, choose **Edit**.
 - c. Replace the access policy that's attached to the queue. In it, provide your Amazon SQS ARN, source bucket name, and bucket owner account ID.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "example-statement-ID",  
            "Effect": "Allow",  
            "Principal": "arn:aws:s3:::source-bucket-name",  
            "Action": "s3:PutObject",  
            "Resource": "arn:aws:s3:::source-bucket-name/*"  
        }  
    ]  
}
```

```
        "Principal": {
            "Service": "s3.amazonaws.com"
        },
        "Action": [
            "SQS:SendMessage"
        ],
        "Resource": "SQS-queue-ARN",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:s3::*:awsexamplebucket1"
            },
            "StringEquals": {
                "aws:SourceAccount": "bucket-owner-account-id"
            }
        }
    }
}
```

d. Choose **Save**.

3. (Optional) If the Amazon SQS queue or the Amazon SNS topic is server-side encryption enabled with AWS Key Management Service (AWS KMS), add the following policy to the associated symmetric encryption customer managed key.

You must add the policy to a customer managed key because you cannot modify the AWS managed key for Amazon SQS or Amazon SNS.

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "*"
        }
    ]
}
```

```
]  
}
```

For more information about using SSE for Amazon SQS and Amazon SNS with AWS KMS, see the following:

- [Key management in the Amazon Simple Notification Service Developer Guide](#).
- [Key management in the Amazon Simple Queue Service Developer Guide](#).

4. Note the queue ARN.

The SQS queue that you created is another resource in your AWS account. It has a unique Amazon Resource Name (ARN). You need this ARN in the next step. The ARN is of the following format:

```
arn:aws:sqs:aws-region:account-id:queue-name
```

Step 2: Create an Amazon SNS topic

Follow the steps to create and subscribe to an Amazon SNS topic.

1. Using Amazon SNS console, create a topic. For instructions, see [Creating an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.
2. Subscribe to the topic. For this exercise, use email as the communications protocol. For instructions, see [Subscribing to an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.

You get an email requesting you to confirm your subscription to the topic. Confirm the subscription.

3. Replace the access policy attached to the topic with the following policy. In it, provide your SNS topic ARN, bucket name, and bucket owner's account ID.

```
{  
    "Version": "2012-10-17",  
    "Id": "example-ID",  
    "Statement": [  
        {  
            "Sid": "Example SNS topic policy",  
            "Effect": "Allow",  
            "Principal": "arn:aws:sns:aws-region:account-id:topic-name",  
            "Action": "sns:Publish",  
            "Resource": "arn:aws:sns:aws-region:account-id:topic-name"  
        }  
    ]  
}
```

```
        "Principal": {
            "Service": "s3.amazonaws.com"
        },
        "Action": [
            "SNS:Publish"
        ],
        "Resource": "SNS-topic-ARN",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "StringEquals": {
                "aws:SourceAccount": "bucket-owner-account-id"
            }
        }
    }
}
```

4. Note the topic ARN.

The SNS topic you created is another resource in your AWS account, and it has a unique ARN. You will need this ARN in the next step. The ARN will be of the following format:

`arn:aws:sns:aws-region:account-id:topic-name`

Step 3: Add a notification configuration to your bucket

You can enable bucket notifications either by using the Amazon S3 console or programmatically by using AWS SDKs. Choose any one of the options to configure notifications on your bucket. This section provides code examples using the AWS SDKs for Java and .NET.

Option A: Enable notifications on a bucket using the console

Using the Amazon S3 console, add a notification configuration requesting Amazon S3 to do the following:

- Publish events of the **All object create events** type to your Amazon SQS queue.
- Publish events of the **Object in RRS lost** type to your Amazon SNS topic.

After you save the notification configuration, Amazon S3 posts a test message, which you get via email.

For instructions, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Option B: Enable notifications on a bucket using the AWS SDKs

.NET

The following C# code example provides a complete code listing that adds a notification configuration to a bucket. You must update the code and provide your bucket name and SNS topic ARN. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class EnableNotificationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string snsTopic = "*** SNS topic ARN ***";
        private const string sqsQueue = "*** SQS topic ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            EnableNotificationAsync().Wait();
        }

        static async Task EnableNotificationAsync()
        {
            try
            {
```

```
        PutBucketNotificationRequest request = new
PutBucketNotificationRequest
{
    BucketName = bucketName
};

TopicConfiguration c = new TopicConfiguration
{
    Events = new List<EventType> { EventType.ObjectCreatedCopy },
    Topic = snsTopic
};
request.TopicConfigurations = new List<TopicConfiguration>();
request.TopicConfigurations.Add(c);
request.QueueConfigurations = new List<QueueConfiguration>();
request.QueueConfigurations.Add(new QueueConfiguration()
{
    Events = new List<EventType> { EventType.ObjectCreatedPut },
    Queue = sqsQueue
});

PutBucketNotificationResponse response = await
client.PutBucketNotificationAsync(request);
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered on server. Message:'{0}' ", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown error encountered on server. Message:'{0}' ", e.Message);
}
}
```

Java

The following example shows how to add a notification configuration to a bucket. For instructions on how to create and test a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.s3.AmazonS3;
import com.amazonaws.services.s3.AmazonS3ClientBuilder;
import com.amazonaws.services.s3.model.*;

import java.io.IOException;
import java.util.EnumSet;

public class EnableNotificationOnABucket {

    public static void main(String[] args) throws IOException {
        String bucketName = "*** Bucket name ***";
        Regions clientRegion = Regions.DEFAULT_REGION;
        String snsTopicARN = "*** SNS Topic ARN ***";
        String sqsQueueARN = "*** SQS Queue ARN ***";

        try {
            AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(clientRegion)
                .build();
            BucketNotificationConfiguration notificationConfiguration = new
BucketNotificationConfiguration();

            // Add an SNS topic notification.
            notificationConfiguration.addConfiguration("snsTopicConfig",
                new TopicConfiguration(snsTopicARN,
EnumSet.of(S3Event.ObjectCreated)));

            // Add an SQS queue notification.
            notificationConfiguration.addConfiguration("sqsQueueConfig",
                new QueueConfiguration(sqsQueueARN,
EnumSet.of(S3Event.ObjectCreated)));

            // Create the notification configuration request and set the bucket
notification
            // configuration.
            SetBucketNotificationConfigurationRequest request = new
SetBucketNotificationConfigurationRequest(
```

```
        bucketName, notificationConfiguration);
    s3Client.setBucketNotificationConfiguration(request);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it, so it returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Step 4: Test the setup

Now, you can test the setup by uploading an object to your bucket and verifying the event notification in the Amazon SQS console. For instructions, see [Receiving a Message](#) in the *Amazon Simple Queue Service Developer Guide "Getting Started"* section.

Configuring event notifications using object key name filtering

When configuring an Amazon S3 event notification, you must specify which supported Amazon S3 event types cause Amazon S3 to send the notification. If an event type that you didn't specify occurs in your S3 bucket, Amazon S3 doesn't send the notification.

You can configure notifications to be filtered by the prefix and suffix of the key name of objects. For example, you can set up a configuration where you're sent a notification only when image files with a ".jpg" file name extension are added to a bucket. Or, you can have a configuration that delivers a notification to an Amazon SNS topic when an object with the prefix "images/" is added to the bucket, while having notifications for objects with a "logs/" prefix in the same bucket delivered to an AWS Lambda function.

Note

A wildcard character ("*") can't be used in filters as a prefix or suffix. If your prefix or suffix contains a space, you must replace it with the "+" character. If you use any other special characters in the value of the prefix or suffix, you must enter them in [URL-encoded \(percent-encoded\) format](#). For a complete list of special characters that must be converted

to URL-encoded format when used in a prefix or suffix for event notifications, see [Safe characters](#).

You can set up notification configurations that use object key name filtering in the Amazon S3 console. You can do so by using Amazon S3 APIs through the AWS SDKs or the REST APIs directly. For information about using the console UI to set a notification configuration on a bucket, see [Enabling and configuring event notifications using the Amazon S3 console](#).

Amazon S3 stores the notification configuration as XML in the *notification* subresource associated with a bucket as described in [Using Amazon SQS, Amazon SNS, and Lambda](#). You use the Filter XML structure to define the rules for notifications to be filtered by the prefix or suffix of an object key name. For information about the Filter XML structure, see [PUT Bucket notification](#) in the *Amazon Simple Storage Service API Reference*.

Notification configurations that use Filter cannot define filtering rules with overlapping prefixes, overlapping suffixes, or prefix and suffix overlapping. The following sections have examples of valid notification configurations with object key name filtering. They also contain examples of notification configurations that are not valid because of prefix and suffix overlapping.

Topics

- [Examples of valid notification configurations with object key name filtering](#)
- [Examples of notification configurations with invalid prefix and suffix overlapping](#)

Examples of valid notification configurations with object key name filtering

The following notification configuration contains a queue configuration identifying an Amazon SQS queue for Amazon S3 to publish events to of the s3:ObjectCreated:Put type. The events are published whenever an object that has a prefix of `images/` and a jpg suffix is PUT to a bucket.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images/</Value>
```

```
</FilterRule>
<FilterRule>
    <Name>suffix</Name>
    <Value>jpg</Value>
</FilterRule>
</S3Key>
</Filter>
<Queue>arn:aws:sqs:us-west-2:444455556666:s3notificationqueue</Queue>
<Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping prefixes. The configuration defines that notifications for PUT requests in the `images/` folder go to queue-A, while notifications for PUT requests in the `logs/` folder go to queue-B.

```
<NotificationConfiguration>
<QueueConfiguration>
    <Id>1</Id>
    <Filter>
        <S3Key>
            <FilterRule>
                <Name>prefix</Name>
                <Value>images/</Value>
            </FilterRule>
        </S3Key>
    </Filter>
    <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-A</Queue>
    <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
<QueueConfiguration>
    <Id>2</Id>
    <Filter>
        <S3Key>
            <FilterRule>
                <Name>prefix</Name>
                <Value>logs/</Value>
            </FilterRule>
        </S3Key>
    </Filter>
    <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-B</Queue>
    <Event>s3:ObjectCreated:Put</Event>
</QueueConfiguration>
```

```
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping suffixes. The configuration defines that all .jpg images newly added to the bucket are processed by Lambda cloud-function-A, and all newly added .png images are processed by cloud-function-B. The .png and .jpg suffixes aren't overlapping even though they have the same last letter. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can't end with both .png and .jpg, so the suffixes in the example configuration aren't overlapping suffixes.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
          <Value>.jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</
CloudFunction>
    <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
  <CloudFunctionConfiguration>
    <Id>2</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
          <Value>.png</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-B</
CloudFunction>
    <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
</NotificationConfiguration>
```

Your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes for the same event types. They can only do so, if the overlapping prefixes that are used

with suffixes that don't overlap. The following example configuration shows how objects created with a common prefix but non-overlapping suffixes can be delivered to different destinations.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>images</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>.jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</CloudFunction>
      <Event>s3:ObjectCreated:Put</Event>
    </CloudFunctionConfiguration>
    <CloudFunctionConfiguration>
      <Id>2</Id>
      <Filter>
        <S3Key>
          <FilterRule>
            <Name>prefix</Name>
            <Value>images</Value>
          </FilterRule>
          <FilterRule>
            <Name>suffix</Name>
            <Value>.png</Value>
          </FilterRule>
        </S3Key>
      </Filter>
      <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-B</CloudFunction>
        <Event>s3:ObjectCreated:Put</Event>
      </CloudFunctionConfiguration>
    </NotificationConfiguration>
```

Examples of notification configurations with invalid prefix and suffix overlapping

For the most part, your notification configurations that use Filter can't define filtering rules with overlapping prefixes, overlapping suffixes, or overlapping combinations of prefixes and suffixes for the same event types. You can have overlapping prefixes as long as the suffixes don't overlap. For an example, see [Configuring event notifications using object key name filtering](#).

You can use overlapping object key name filters with different event types. For example, you can create a notification configuration that uses the prefix `image/` for the `ObjectCreated:Put` event type and the prefix `image/` for the `ObjectRemoved:*` event type.

You get an error if you try to save a notification configuration that has invalid overlapping name filters for the same event types when using the Amazon S3 console or API. This section shows examples of notification configurations that aren't valid because of overlapping name filters.

Any existing notification configuration rule is assumed to have a default prefix and suffix that match any other prefix and suffix, respectively. The following notification configuration isn't valid because it has overlapping prefixes. Specifically, the root prefix overlaps with any other prefix. The same thing is true if you use a suffix instead of a prefix in this example. The root suffix overlaps with any other suffix.

```
<NotificationConfiguration>
    <TopicConfiguration>
        <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-one</Topic>
        <Event>s3:ObjectCreated:*</Event>
    </TopicConfiguration>
    <TopicConfiguration>
        <Topic>arn:aws:sns:us-west-2:44445556666:sns-notification-two</Topic>
        <Event>s3:ObjectCreated:*</Event>
        <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
            </S3Key>
        </Filter>
    </TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping suffixes. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can end with jpg and pg. So, the suffixes overlap. The same is true for prefixes. If a given string can begin with both prefixes, the two prefixes are considered overlapping.

```
<NotificationConfiguration>
  <TopicConfiguration>
    <Topic>arn:aws:sns:us-west-2:444455556666:sns-topic-one</Topic>
    <Event>s3:ObjectCreated:*</Event>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>suffix</Name>
          <Value>jpg</Value>
        </FilterRule>
      </S3Key>
    </Filter>
  </TopicConfiguration>

            <FilterRule>
                <Name>suffix</Name>
                <Value>jpg</Value>
            </FilterRule>
        </S3Key>
    </Filter>
</TopicConfiguration>
</NotificationConfiguration>
```

Event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format.

For a general overview and instructions on configuring event notifications, see [Amazon S3 Event Notifications](#).

This example shows *version 2.2* of the event notification JSON structure. Amazon S3 uses *versions 2.1, 2.2, and 2.3* of this event structure. Amazon S3 uses version 2.2 for cross-Region replication event notifications. It uses version 2.3 for S3 Lifecycle, S3 Intelligent-Tiering, object ACL, object tagging, and object restoration delete events. These versions contain extra information specific to these operations. Versions 2.2 and 2.3 are otherwise compatible with version 2.1, which Amazon S3 currently uses for all other event notification types.

```
{
    "Records": [
        {
            "eventVersion": "2.2",
            "eventSource": "aws:s3",
```

```
        "awsRegion": "us-west-2",
        "eventTime": "The time, in ISO-8601 format, for example,  
1970-01-01T00:00:00.000Z, when Amazon S3 finished processing the request",
        "eventName": "event-type",
        "userIdentity": {
            "principalId": "Amazon-customer-ID-of-the-user-who-caused-the-event"
        },
        "requestParameters": {
            "sourceIPAddress": "ip-address-where-request-came-from"
        },
        "responseElements": {
            "x-amz-request-id": "Amazon S3 generated request ID",
            "x-amz-id-2": "Amazon S3 host that processed the request"
        },
        "s3": {
            "s3SchemaVersion": "1.0",
            "configurationId": "ID found in the bucket notification configuration",
            "bucket": {
                "name": "amzn-s3-demo-bucket",
                "ownerIdentity": {
                    "principalId": "Amazon-customer-ID-of-the-bucket-owner"
                },
                "arn": "bucket-ARN"
            },
            "object": {
                "key": "object-key",
                "size": "object-size in bytes",
                "eTag": "object eTag",
                "versionId": "object version if bucket is versioning-enabled, otherwise  
null",
                "sequencer": "a string representation of a hexadecimal value used to  
determine event sequence, only used with PUTs and DELETEs"
            }
        },
        "glacierEventData": {
            "restoreEventData": {
                "lifecycleRestorationExpiryTime": "The time, in ISO-8601 format, for  
example, 1970-01-01T00:00:00.000Z, of Restore Expiry",
                "lifecycleRestoreStorageClass": "Source storage class for restore"
            }
        }
    }
]
```

}

Note the following about the event message structure:

- The `eventVersion` key value contains a major and minor version in the form `<major>.<minor>`.

The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

The minor version is incremented if Amazon S3 adds new fields to the event structure. This might occur if new information is provided for some or all existing events. This might also occur if new information is provided on only newly introduced event types. Applications should ignore new fields to stay forward compatible with new minor versions of the event structure.

If new event types are introduced but the structure of the event is otherwise unmodified, the event version doesn't change.

To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.

- The `eventName` references the list of [event notification types](#) but doesn't contain the `s3:` prefix.
- The `responseElements` key value is useful if you want to trace a request by following up with AWS Support. Both `x-amz-request-id` and `x-amz-id-2` help Amazon S3 trace an individual request. These values are the same as those that Amazon S3 returns in the response to the request that initiates the events. This is so they can be used to match the event to the request.
- The `s3` key provides information about the bucket and object involved in the event. The object key name value is URL encoded. For example, "red flower.jpg" becomes "red+flower.jpg" (Amazon S3 returns "application/x-www-form-urlencoded" as the content type in the response).
- The `sequencer` key provides a way to determine the sequence of events. Event notifications aren't guaranteed to arrive in the same order that the events occurred. However, notifications from events that create objects (PUTs) and delete objects contain a `sequencer`. It can be used to determine the order of events for a given object key.

If you compare the `sequencer` strings from two event notifications on the same object key, the event notification with the greater `sequencer` hexadecimal value is the event that occurred

later. If you're using event notifications to maintain a separate database or index of your Amazon S3 objects, we recommend that you compare and store the `sequencer` values as you process each event notification.

Note the following:

- You can't use `sequencer` to determine order for events on different object keys.
- The sequencers can be of different lengths. So, to compare these values, first right pad the shorter value with zeros, and then do a lexicographical comparison.
- The `glacierEventData` key is only visible for `s3:ObjectRestore:Completed` events.
- The `restoreEventData` key contains attributes that are related to your restore request.
- The `replicationEventData` key is only visible for replication events.
- The `intelligentTieringEventData` key is only visible for S3 Intelligent-Tiering events.
- The `lifecycleEventData` key is only visible for S3 Lifecycle transition events.

Example messages

The following are examples of Amazon S3 event notification messages.

Amazon S3 test message

After you configure an event notification on a bucket, Amazon S3 sends the following test message.

```
{  
    "Service": "Amazon S3",  
    "Event": "s3:TestEvent",  
    "Time": "2014-10-13T15:57:02.089Z",  
    "Bucket": "amzn-s3-demo-bucket",  
    "RequestId": "5582815E1AEA5ADF",  
    "HostId": "8cLeGAmw098X5cv4Zkwcmo8vvZa3eH3eKxsPzbB9wrR+YstdA6Knx4Ip8EXAMPLE"  
}
```

Example message when an object is created using a PUT request

The following message is an example of a message Amazon S3 sends to publish an `s3:ObjectCreated:Put` event.

```
{
```

```
"Records": [
    {
        "eventVersion": "2.1",
        "eventSource": "aws:s3",
        "awsRegion": "us-west-2",
        "eventTime": "1970-01-01T00:00:00.000Z",
        "eventName": "ObjectCreated:Put",
        "userIdentity": {
            "principalId": "AIDAJDPLRKLG7UEXAMPLE"
        },
        "requestParameters": {
            "sourceIPAddress": "127.0.0.1"
        },
        "responseElements": {
            "x-amz-request-id": "C3D13FE58DE4C810",
            "x-amz-id-2": "FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvAN0jpD"
        },
        "s3": {
            "s3SchemaVersion": "1.0",
            "configurationId": "testConfigRule",
            "bucket": {
                "name": "amzn-s3-demo-bucket",
                "ownerIdentity": {
                    "principalId": "A3NL1K0ZZKExample"
                },
                "arn": "arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "object": {
                "key": "HappyFace.jpg",
                "size": 1024,
                "eTag": "d41d8cd98f00b204e9800998ecf8427e",
                "versionId": "096fKKXTRTt13on89fV0.nfljtsv6qko",
                "sequencer": "0055AED6DCD90281E5"
            }
        }
    }
]
```

For a definition of each IAM identification prefix (for example, AIDA, AROA, AGPA), see [IAM identifiers](#) in the *IAM User Guide*.

Using EventBridge

Amazon S3 can send events to Amazon EventBridge whenever certain events happen in your bucket. Unlike other destinations, you don't need to select which event types you want to deliver. After EventBridge is enabled, all events below are sent to EventBridge. You can use EventBridge rules to route events to additional targets. The following lists the events Amazon S3 sends to EventBridge.

Event type	Description
<i>Object Created</i>	<p>An object was created.</p> <p>The reason field in the event message structure indicates which S3 API was used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload.</p>
<i>Object Deleted (DeleteObject)</i>	<p>An object was deleted.</p>
<i>Object Deleted (Lifecycle expiration)</i>	<p>When an object is deleted using an S3 API call, the reason field is set to DeleteObject. When an object is deleted by an S3 Lifecycle expiration rule, the reason field is set to Lifecycle Expiration. For more information, see Expiring objects.</p> <p>When an unversioned object is deleted, or a versioned object is permanently deleted, the deletion-type field is set to Permanently Deleted. When a delete marker is created for a versioned object, the deletion-type field is set to Delete Marker Created. For more information, see Deleting object versions from a versioning-enabled bucket.</p>
<i>Object Restore Initiated</i>	<p>An object restore was initiated from S3 Glacier or S3 Glacier Deep Archive storage class or from S3 Intelligent-Tiering Archive Access or Deep Archive Access tier. For more information, see Working with archived objects.</p>
<i>Object Restore Completed</i>	<p>An object restore was completed.</p>

Event type	Description
<i>Object Restore Expired</i>	The temporary copy of an object restored from S3 Glacier or S3 Glacier Deep Archive expired and was deleted.
<i>Object Storage Class Changed</i>	An object was transitioned to a different storage class. For more information, see Transitioning objects using Amazon S3 Lifecycle .
<i>Object Access Tier Changed</i>	An object was transitioned to the S3 Intelligent-Tiering Archive Access tier or Deep Archive Access tier. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering .
<i>Object ACL Updated</i>	An object's access control list (ACL) was set using PutObjectACL. An event is not generated when a request results in no change to an object's ACL. For more information, see Access control list (ACL) overview .
<i>Object Tags Added</i>	A set of tags was added to an object using PutObject Tagging. For more information, see Categorizing your storage using tags .
<i>Object Tags Deleted</i>	All tags were removed from an object using DeleteObjectTagging. For more information, see Categorizing your storage using tags .

 **Note**

For more information about how Amazon S3 event types map to EventBridge event types, see [Amazon EventBridge mapping and troubleshooting](#).

You can use Amazon S3 Event Notifications with EventBridge to write rules that take actions when an event occurs in your bucket. For example, you can have it send you a notification. For more information, see [What is EventBridge](#) in the *Amazon EventBridge User Guide*.

For more information about the actions and data types you can interact with using the EventBridge API, see the [Amazon EventBridge API Reference](#) in the *Amazon EventBridge API Reference*.

For information about pricing, see [Amazon EventBridge pricing](#).

Topics

- [Amazon EventBridge permissions](#)
- [Enabling Amazon EventBridge](#)
- [EventBridge event message structure](#)
- [Amazon EventBridge mapping and troubleshooting](#)

Amazon EventBridge permissions

Amazon S3 does not require any additional permissions to deliver events to Amazon EventBridge.

Enabling Amazon EventBridge

You can enable Amazon EventBridge using the S3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API.

Using the S3 console

To enable EventBridge event delivery in the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and find the **Amazon EventBridge** subsection. Choose **Edit**.
6. Under **Send notifications to Amazon EventBridge for all events in this bucket** choose **On**.

 **Note**

After you enable EventBridge, it takes around five minutes for the changes to take effect.

Using the AWS CLI

The following example creates a bucket notification configuration for bucket amzn-s3-demo-bucket1 with Amazon EventBridge enabled.

```
aws s3api put-bucket-notification-configuration --bucket amzn-s3-demo-bucket1 --notification-configuration='{"EventBridgeConfiguration": {} }'
```

Using the REST API

You can programmatically enable Amazon EventBridge on a bucket by calling the Amazon S3 REST API. For more information see, [PutBucketNotificationConfiguration](#) in the *Amazon Simple Storage Service API Reference*.

The following example shows the XML used to create a bucket notification configuration with Amazon EventBridge enabled.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <EventBridgeConfiguration>
  </EventBridgeConfiguration>
</NotificationConfiguration>
```

Creating EventBridge rules

Once enabled you can create Amazon EventBridge rules for certain tasks. For example, you can send email notifications when an object is created. For a full tutorial, see [Tutorial: Send a notification when an Amazon S3 object is created](#) in the *Amazon EventBridge User Guide*.

EventBridge event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format. When Amazon S3 sends an event to Amazon EventBridge, the following fields are present.

- **version** — Currently 0 (zero) for all events.
- **id** — A UUID generated for every event.
- **detail-type** — The type of event that's being sent. See [Using EventBridge](#) for a list of event types.
- **source** — Identifies the service that generated the event.
- **account** — The 12-digit AWS account ID of the bucket owner.

- **time** — The time the event occurred.
- **region** — Identifies the AWS Region of the bucket.
- **resources** — A JSON array that contains the Amazon Resource Name (ARN) of the bucket.
- **detail** — A JSON object that contains information about the event. For more information about what can be included in this field, see [Event message detail field](#).

Event message structure examples

The following are examples of some of the Amazon S3 event notification messages that can be sent to Amazon EventBridge.

Object created

```
{  
    "version": "0",  
    "id": "17793124-05d4-b198-2fde-7edede63b103",  
    "detail-type": "Object Created",  
    "source": "aws.s3",  
    "account": "111122223333",  
    "time": "2021-11-12T00:00:00Z",  
    "region": "ca-central-1",  
    "resources": [  
        "arn:aws:s3:::amzn-s3-demo-bucket1"  
    ],  
    "detail": {  
        "version": "0",  
        "bucket": {  
            "name": "amzn-s3-demo-bucket1"  
        },  
        "object": {  
            "key": "example-key",  
            "size": 5,  
            "etag": "b1946ac92492d2347c6235b4d2611184",  
            "version-id": "IYV3p45BT0ac8hjHg1houSdS1a.Mro8e",  
            "sequencer": "617f08299329d189"  
        },  
        "request-id": "N4N7GDK58NMKJ12R",  
        "requester": "123456789012",  
        "source-ip-address": "1.2.3.4",  
        "reason": "PutObject"  
    }  
}
```

```
}
```

Object deleted (using DeleteObject)

```
{
  "version": "0",
  "id": "2ee9cc15-d022-99ea-1fb8-1b1bac4850f9",
  "detail-type": "Object Deleted",

Event message detail field

The detail field contains a JSON object with information about the event. The following fields may be present in the detail field.

- **version** — Currently 0 (zero) for all events.
- **bucket** — Information about the Amazon S3 bucket involved in the event.
- **object** — Information about the Amazon S3 object involved in the event.
- **request-id** — Request ID in S3 response.
- **requester** — AWS account ID or AWS service principal of requester.
- **source-ip-address** — Source IP address of S3 request. Only present for events triggered by an S3 request.
- **reason** — For **Object Created** events, the S3 API used to create the object: [PutObject](#), [POST Object](#), [CopyObject](#), or [CompleteMultipartUpload](#). For **Object Deleted** events, this is set to **DeleteObject** when an object is deleted by an S3 API call, or **Lifecycle Expiration** when an object is deleted by an S3 Lifecycle expiration rule. For more information, see [Expiring objects](#).
- **deletion-type** — For **Object Deleted** events, when an unversioned object is deleted, or a versioned object is permanently deleted, this is set to **Permanently Deleted**. When a delete marker is created for a versioned object, this is set to **Delete Marker Created**. For more information, see [Deleting object versions from a versioning-enabled bucket](#).

Note

Some object attributes (such as etag and size) are present only when a delete marker is created.

- **restore-expiry-time** — For **Object Restore Completed** events, the time when the temporary copy of the object will be deleted from S3. For more information, see [Working with archived objects](#).
- **source-storage-class** — For **Object Restore Initiated** and **Object Restore Completed** events, the storage class of the object being restored. For more information, see [Working with archived objects](#).
- **destination-storage-class** — For **Object Storage Class Changed** events, the new storage class of the object. For more information, see [Transitioning objects using Amazon S3 Lifecycle](#).
- **destination-access-tier** — For **Object Access Tier Changed** events, the new access tier of the object. For more information, see [Managing storage costs with Amazon S3 Intelligent-Tiering](#).

Amazon EventBridge mapping and troubleshooting

The following table describes how Amazon S3 event types are mapped to Amazon EventBridge event types.

S3 event type	Amazon EventBridge detail type
ObjectCreated:Put	Object Created
ObjectCreated:Post	
ObjectCreated:Copy	
ObjectCreated:CompleteMultiPartUpload	
ObjectRemoved:Delete	Object Deleted
ObjectRemoved:DeleteMarkerCreated	

S3 event type	Amazon EventBridge detail type
LifecycleExpiration:Delete	
LifecycleExpiration:DeleteMarkerCreated	
<u>ObjectRestore:Post</u>	Object Restore Initiated
ObjectRestore:Completed	Object Restore Completed
ObjectRestore:Delete	Object Restore Expired
LifecycleTransition	Object Storage Class Changed
IntelligentTiering	Object Access Tier Changed
<u>ObjectTagging:Put</u>	Object Tags Added
<u>ObjectTagging:Delete</u>	Object Tags Deleted
<u>ObjectAcl:Put</u>	Object ACL Updated

Amazon EventBridge troubleshooting

For information about how to troubleshoot EventBridge, see [Troubleshooting Amazon EventBridge](#) in the *Amazon EventBridge User Guide*.

Assessing your storage activity and usage with Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object storage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use S3 Storage Lens metrics to generate summary insights. For example, you can find out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization

opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to abort incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

S3 Storage Lens metrics and features

S3 Storage Lens provides an interactive *default dashboard* that is updated daily. S3 Storage Lens preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. Metrics from this dashboard are also summarized in your account snapshot on the **Buckets** page. For more information, see [Default dashboard](#).

To create other dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations), you create an S3 Storage Lens dashboard configuration. You can create and manage S3 Storage Lens dashboard configurations by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These features include advanced metric categories, prefix aggregation, contextual recommendations, and Amazon CloudWatch publishing. Prefix aggregation and contextual recommendations are available only in the Amazon S3 console. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Metrics categories

Within the free and advanced tiers, metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable advanced cost-optimization and data-protection metrics. You can use these advanced metrics to further reduce your S3 storage costs and improve your data-protection stance. You can also enable activity metrics and detailed status-code metrics to improve the performance of application workloads that are accessing your S3 buckets. For more information about the free and advanced metrics categories, see [Metrics selection](#).

You can assess your storage based on S3 best practices, such as analyzing the percentage of your buckets that have encryption or S3 Object Lock or S3 Versioning enabled. You can also identify potential cost-savings opportunities. For example, you can use S3 Lifecycle rule count metrics to identify buckets that are missing lifecycle expiration or transition rules. You can also analyze your request activity per bucket to find buckets where objects could be transitioned to a lower-cost storage class. For more information, see [Amazon S3 Storage Lens metrics use cases](#).

Metrics export

In addition to viewing the dashboard on the S3 console, you can export metrics in CSV or Parquet format to an S3 bucket for further analysis with the analytics tool of your choice. For more information, see [Viewing Amazon S3 Storage Lens metrics using a data export](#).

Amazon CloudWatch publishing

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens.

advanced metrics and recommendations. For more information about support for S3 Storage Lens metrics in CloudWatch, see [Monitor S3 Storage Lens metrics in CloudWatch](#).

For more information about using S3 Storage Lens, see the following topics.

Understanding Amazon S3 Storage Lens

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best

practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. You can create and manage S3 Storage Lens dashboards by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

S3 Storage Lens concepts and terminology

This section contains the terminology and concepts that are essential for successfully understanding and using Amazon S3 Storage Lens.

Topics

- [Dashboard configuration](#)
- [Default dashboard](#)
- [Dashboards](#)
- [Account snapshot](#)
- [Metrics export](#)
- [Home Region](#)
- [Retention period](#)
- [Metrics categories](#)
- [Recommendations](#)
- [Metrics selection](#)
- [S3 Storage Lens and AWS Organizations](#)

Dashboard configuration

S3 Storage Lens requires a dashboard configuration that contains the properties required to aggregate metrics on your behalf for a single dashboard or export. When you create a

configuration, you choose the dashboard name and the home Region, which you can't change after you create the dashboard. You can optionally add tags and configure a metrics export in CSV or Parquet format.

In the dashboard configuration, you also define the dashboard scope and the metrics selection. The scope can include all the storage for your organization account or sections that are filtered by Region, bucket, and account. When you configure the metrics selection, you choose between free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

Default dashboard

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. S3 preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from free metrics to advanced metrics and recommendations. You can configure the optional metrics export or even disable the dashboard. However, you can't delete the default dashboard.

Note

If you disable your default dashboard, it is no longer updated. You'll no longer receive any new daily metrics in your S3 Storage Lens dashboard, your metrics export, or the account snapshot on the [S3 Buckets](#) page. If your dashboard uses advanced metrics and recommendations, you'll no longer be charged. You can still see historic data in the dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access historic data, you can re-enable the dashboard within the expiration period.

Dashboards

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations). When you create or edit a S3 Storage Lens dashboard, you define your dashboard scope and metrics selection. S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional

charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see [Amazon S3 pricing](#).

You can also disable or delete dashboards. If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access historic data, you can re-enable the dashboard within the expiration period.

If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

Note

- You can use S3 Storage Lens to create up to 50 dashboards per home Region.
- Organization-level dashboards can be limited only to a Regional scope.

Account snapshot

The S3 Storage Lens **Account snapshot** summarizes metrics from your default dashboard and displays your total storage, object count, and average object size on the S3 console **Buckets** page. This account snapshot gives you quick access to insights about your storage without having to leave the **Buckets** page. The account snapshot also provides one-click access to your interactive S3 Storage Lens dashboard.

You can use your dashboard to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the organization, account, bucket, object, or prefix level. You can also send a once-daily metrics export to an S3 bucket in CSV or Parquet format.

You can't modify the dashboard scope of the **default-account dashboard** because it's linked to the **Account snapshot**. However, you can upgrade the metrics selection in your **default-account-**

dashboard from free metrics to paid advanced metrics and recommendations. After upgrading, you can then display all requests, bytes uploaded, and bytes downloaded in the S3 Storage Lens **Account snapshot**.

Note

If you disable your default dashboard, your **Account snapshot** is no longer updated. To continue displaying metrics in the **Account snapshot**, you can re-enable the **default-account-dashboard**.

Metrics export

An S3 Storage Lens metrics export is a file that contains all the metrics identified in your S3 Storage Lens configuration. This information is generated daily in CSV or Parquet format and is sent to an S3 bucket. You can use the metrics export for further analysis by using the metrics tool of your choice. The S3 bucket for your metrics export must be in the same Region as your S3 Storage Lens configuration. You can generate an S3 Storage Lens metrics export from the S3 console by editing your dashboard configuration. You can also configure a metrics export by using the AWS CLI and AWS SDKs.

Home Region

The home Region is the AWS Region where all S3 Storage Lens metrics for a given dashboard configuration are stored. You must choose a home Region when you create your S3 Storage Lens dashboard configuration. After you choose a home Region, you can't change it. Also, if you're creating a Storage Lens group, we recommend that you choose the same home Region as your Storage Lens dashboard.

Note

You can choose one of the following Regions as your home Region:

- US East (N. Virginia) – us-east-1
- US East (Ohio) – us-east-2
- US West (N. California) – us-west-1
- US West (Oregon) – us-west-2
- Asia Pacific (Mumbai) – ap-south-1

- Asia Pacific (Seoul) – ap-northeast-2
- Asia Pacific (Singapore) – ap-southeast-1
- Asia Pacific (Sydney) – ap-southeast-2
- Asia Pacific (Tokyo) – ap-northeast-1
- Canada (Central) – ca-central-1
- China (Beijing) – cn-north-1
- China (Ningxia) – cn-northwest-1
- Europe (Frankfurt) – eu-central-1
- Europe (Ireland) – eu-west-1
- Europe (London) – eu-west-2
- Europe (Paris) – eu-west-3
- Europe (Stockholm) – eu-north-1
- South America (São Paulo) – sa-east-1

Retention period

S3 Storage Lens metrics are retained so that you can see historical trends and compare differences in your storage and activity over time. You can use Amazon S3 Storage Lens metrics for queries so that you can see historical trends and compare differences in your storage usage and activity over time.

All S3 Storage Lens metrics are retained for a period of 15 months. However, metrics are only available for queries for a specific duration, which depends on your [metrics selection](#). This duration can't be modified. Free metrics are available for queries for a 14-day period, and advanced metrics are available for queries for a 15-month period.

Metrics categories

Within the free and advanced tiers, S3 Storage Lens metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable additional cost-optimization and data-protection metrics that you can use to further reduce your S3 storage costs and ensure your data is protected. You can also enable activity metrics and detailed status-code metrics that you can use to improve the performance of application workflows.

The following list shows all of the free and advanced metric categories. For a complete list of the individual metrics included in each category, see [Metrics glossary](#).

Summary metrics

Summary metrics provide general insights about your S3 storage, including your total storage bytes and object count.

Cost-optimization metrics

Cost-optimization metrics provide insights that you can use to manage and optimize your storage costs. For example, you can identify buckets that have incomplete multipart uploads that are more than 7-days old.

With advanced metrics and recommendations, you can enable advanced cost-optimization metrics. These metrics include S3 Lifecycle rule count metrics that you can use to get per-bucket expiration and transition S3 Lifecycle rule counts.

Data-protection metrics

Data-protection metrics provide insights for data-protection features, such as encryption and S3 Versioning. You can use these metrics to identify buckets that are not following data-protection best practices. For example, you can identify buckets that are not using default encryption with AWS Key Management Service keys (SSE-KMS) or S3 Versioning.

With advanced metrics and recommendations, you can enable advanced data-protection metrics. These metrics include per-bucket replication rule count metrics.

Access-management metrics

Access-management metrics provide insights for S3 Object Ownership. You can use these metrics to see which Object Ownership settings your buckets use.

Event metrics

Event metrics provide insights for S3 Event Notifications. With event metrics, you can see which buckets have S3 Event Notifications configured.

Performance metrics

Performance metrics provide insights for S3 Transfer Acceleration. With performance metrics, you can see which buckets have Transfer Acceleration enabled.

Activity metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable activity metrics. Activity metrics provide details about how your storage is requested (for example, All requests, Get requests, Put requests), Bytes uploaded or downloaded, and errors.

Prefix-level activity metrics can be used to help you determine which prefixes are being used infrequently, so that you can [transition to a more optimal storage class using S3 Lifecycle](#).

Detailed status code metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable detailed status code metrics. Detailed status code metrics provide insights for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable, that you can use to troubleshoot access or performance issues. For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied.

Prefix-level detailed status code metrics can be used to gain a better understanding of the HTTP status code occurrences by prefix. For example, 503 error count metrics enable you to identify prefixes receiving throttling requests during data ingestion.

Recommendations

S3 Storage Lens provides automated recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the S3 Storage Lens dashboard. Historical data is not eligible for recommendations because recommendations are relevant to what is happening in the most recent period. Recommendations appear only when they are relevant.

S3 Storage Lens recommendations come in the following forms:

- **Suggestions**

Suggestions alert you to trends within your storage and activity that might indicate a storage-cost optimization opportunity or a data-protection best practice. You can use the suggested topics in the *Amazon S3 User Guide* and the S3 Storage Lens dashboard to drill down for more details about the specific Regions, buckets, or prefixes.

- **Call-outs**

Call-outs are recommendations that alert you to interesting anomalies within your storage and activity over a period that might need further attention or monitoring.

- **Outlier call-outs**

S3 Storage Lens provides call-outs for metrics that are outliers, based on your recent 30-day trend. The outlier is calculated by using a standard score, also known as a *z-score*. In this score, the current day's metric is subtracted from the average of the last 30 days for that metric. The current day's metric is then divided by the standard deviation for that metric over the last 30 days. The resulting score is usually between -3 and +3. This number represents the number of standard deviations that the current day's metric is from the mean.

S3 Storage Lens considers metrics with a score >2 or <-2 to be outliers because they are higher or lower than 95 percent of normally distributed data.

- **Significant change call-outs**

The significant change call-out applies to metrics that are expected to change less frequently. Therefore, it is set to a higher sensitivity than the outlier calculation, which is typically in the range of +/- 20 percent versus the prior day, week, or month.

Addressing call-outs in your storage and activity – If you receive a significant change call-out, it's not necessarily a problem. The call-out could be the result of an anticipated change in your storage. For example, you might have recently added a large number of new objects, deleted a large number of objects, or made similar planned changes.

If you see a significant change call-out on your dashboard, take note of it and determine whether it can be explained by recent circumstances. If not, use the S3 Storage Lens dashboard to drill down for more details to understand the specific Regions, buckets, or prefixes that are driving the fluctuation.

- **Reminders**

Reminders provide insights into how Amazon S3 works. They can help you learn more about ways to use S3 features to reduce storage costs or apply data-protection best practices.

Metrics selection

S3 Storage Lens offers two metrics selections that you can choose for your dashboard and export: *free metrics* and *advanced metrics and recommendations*.

- **Free metrics**

S3 Storage Lens offers free metrics for all dashboards and configurations. Free metrics contain metrics that are relevant to your storage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics (for example, cost-optimization and data-protection metrics) that you can use to investigate whether your storage is configured according to S3 best practices. All free metrics are collected daily. Data is available for queries for 14 days. For more information about which metrics are available with free metrics, see the [Amazon S3 Storage Lens metrics glossary](#).

- **Advanced metrics and recommendations**

S3 Storage Lens offers free metrics for all dashboards and configurations with the option to upgrade to advanced metrics and recommendations. Additional charges apply. For more information, see [Amazon S3 pricing](#).

Advanced metrics and recommendations include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics, activity metrics, and detailed status-code metrics. Advanced metrics and recommendations also provide recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the dashboard.

Advanced metrics and recommendations include the following features:

- **Advanced metrics** – Generate additional metrics. For a complete list of advanced metric categories, see [Metrics categories](#). For a complete list of metrics, see the [Amazon S3 Storage Lens metrics glossary](#).
- **Amazon CloudWatch publishing** – Publishes S3 Storage Lens metrics to CloudWatch to create a unified view of your operational health in CloudWatch [dashboards](#). You can also use CloudWatch API operations and features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. For more information, see [Monitor S3 Storage Lens metrics in CloudWatch](#).
- **Prefix aggregation** – Collects metrics at the [prefix](#) level. Enabling prefix aggregation extends all metrics that are included in your dashboard configuration at the prefix level. Metrics are only generated for prefixes that meet the configured threshold. Note that metrics that are applicable at the prefix level are available with **Prefix aggregation**, except for bucket-level settings and rule count metrics. Prefix-level metrics are not published to CloudWatch.
- **Storage Lens group aggregation** – Collects metrics at the Storage Lens group level. After you enable **Advanced metrics and recommendations** and **Storage Lens group aggregation**, you can specify which Storage Lens groups to include or exclude from your Storage Lens

dashboard. At least one Storage Lens group must be specified. Storage Lens groups that are specified must also reside within the designated home Region in the dashboard account. Storage Lens group-level metrics are not published to CloudWatch.

All advanced metrics are collected daily. Data is available for querying for up to 15 months. For more information about the storage metrics that are aggregated by S3 Storage Lens, see [Amazon S3 Storage Lens metrics glossary](#).

 **Note**

Recommendations are available only when you use the S3 Storage Lens dashboard on the Amazon S3 console.

S3 Storage Lens and AWS Organizations

AWS Organizations is an AWS service that helps you aggregate all of your AWS accounts under one organization hierarchy. Amazon S3 Storage Lens works with AWS Organizations to provide a single view of object storage and activity across your Amazon S3 storage.

For more information, see [Using Amazon S3 Storage Lens with AWS Organizations](#).

- **Trusted access**

Using your organization's management account, you must enable *trusted access* for S3 Storage Lens to aggregate storage metrics and usage data for all member accounts in your organization. You can then create dashboards or exports for your organization by using your management account or by giving delegated administrator access to other accounts in your organization.

You can disable trusted access for S3 Storage Lens at any time, which stops S3 Storage Lens from aggregating metrics for your organization.

- **Delegated administrator**

You can create dashboards and metrics for S3 Storage Lens for your organization by using your AWS Organizations management account, or by giving *delegated administrator* access to other accounts in your organization. You can deregister delegated administrators at any time. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

For more information, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Amazon S3 Storage Lens service-linked roles

Along with AWS Organizations trusted access, Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that it requires to collect daily storage and activity metrics from member accounts in your organization.

For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

Amazon S3 Storage Lens metrics glossary

The Amazon S3 Storage Lens metrics glossary provides a complete list of free and advanced metrics for S3 Storage Lens.

S3 Storage Lens offers free metrics for all dashboards and configurations, with the option to upgrade to advanced metrics.

- **Free metrics** contain metrics that are relevant to your storage usage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics, such as cost-optimization and data-protection metrics. All free metrics are collected daily, and data is available for queries for up to 14 days.
- **Advanced metrics and recommendations** include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics. Advanced metrics also include additional metric categories, such as activity metrics and detailed status-code metrics. Advanced metrics data is available for queries for 15 months.

There are additional charges when you use S3 Storage Lens with advanced metrics and recommendations. For more information, see [Amazon S3 pricing](#). For more information about advanced metrics and recommendations features, see [Metrics selection](#).

 **Note**

For Storage Lens groups, only free tier storage metrics are available. Advanced tier metrics are not available at the Storage Lens group level.

Metric names

The **Metric name** column in the following table provides the name of each S3 Storage Lens in the S3 console. The **CloudWatch and export** column provides the name of each metric in Amazon CloudWatch and the metrics export file that you can configure in your S3 Storage Lens dashboard.

Derived metric formulas

Derived metrics are not available for the metrics export and the CloudWatch publishing option. However, you can use the metrics formulas shown in the **Derived metrics formula** column to compute them.

Interpreting the Amazon S3 Storage Lens prefix symbols for metrics unit multiples (K, M, G, and so on)

S3 Storage Lens metrics unit multiples are written with prefix symbols. These prefix symbols match the International System of Units (SI) symbols that are standardized by the International Bureau of Weights and Measures (BIPM). These symbols are also used in the Unified Code for Units of Measure (UCUM). For more information, see [List of SI prefix symbols](#).

Note

- The unit of measurement for S3 storage bytes is in binary gigabytes (GB), where 1 GB is 2^{30} bytes, 1 TB is 2^{40} bytes, and 1 PB is 2^{50} bytes. This unit of measurement is also known as a gibibyte (GiB), as defined by the International Electrotechnical Commission (IEC).
- When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. S3 Storage Lens doesn't include metrics for objects that have expired but haven't been removed. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).

The following table shows the S3 Storage Lens metrics glossary.

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Detailed metric form
Total storage	StorageBytes	The total storage, inclusive of incomplete multipart uploads, object metadata, and delete markers	Free	Sum	N	-
Object count	ObjectCount	The total object count	Free	Sum	N	-
Average object size	-	The average object size	Free	Sum	Y	$\text{sum(StorageBytes)}/\text{sum(ObjectCount)}$
Active buckets	-	The total number of buckets with storage > 0 bytes	Free	Sum	Y	-
Buckets	-	The total number of buckets	Free	Sum	Y	-
Accounts	-	The number of accounts whose storage is in scope	Free	Sum	Y	-
Current version bytes	CurrentVersionStorageBytes	The number of bytes that are a current version of an object	Free	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
% current version bytes	-	The percentage of bytes in scope that are current versions of objects	Free	Cost optimization	Y	sum(CurrentVersionStorageBytes)/sum(StorageBytes)	
Current version object count	CurrentVersionObjectCount	The count of current version objects	Free	Data protection	N	-	
% current version objects	-	The percentage of objects in scope that are a current version	Free	Cost optimization	Y	sum(CurrentVersionObjectCount)/sum(ObjectCount)	
Noncurrent version bytes	NonCurrentVersionStorageBytes	The number of noncurrent version bytes	Free	Cost optimization	N	-	
% noncurrent version bytes	-	The percentage of bytes in scope that are noncurrent versions	Free	Cost optimization	Y	sum(NonCurrentVersionStorageBytes)/sum(StorageBytes)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
Noncurrent version object count	NonCurrentVersionObjectCount	The count of the noncurrent object versions	Free	Cost optimization	N	-
% noncurrent version objects	-	The percentage of objects in scope that are a noncurrent version	Free	Cost optimization	Y	$\text{sum}(\text{NonCurrentVersionObjectCount})/\text{sum}(\text{ObjectCount})$
Delete marker bytes	DeleteMarkerStorageBytes	The number of bytes in scope that are delete markers	Free	Cost optimization	N	-
% delete marker bytes	-	The percentage of bytes in scope that are delete markers	Free	Cost optimization	Y	$\text{sum}(\text{DeleteMarkerStorageBytes})/\text{sum}(\text{StorageBytes})$
Delete marker object count	DeleteMarkerObjectCount	The total number of objects with a delete marker	Free	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% delete marker objects	-	The percentage of objects in scope with a delete marker	Free	Cost optimization	Y	sum(DeleteMarkerObjectCount) / sum(ObjectCount)	
Incomplete multipart upload bytes	IncompleteMultipartUploadStorageBytes	The total bytes in scope for incomplete multipart uploads	Free	Cost optimization	N	-	
% incomplete multipart upload bytes	-	The percentage of bytes in scope that are the result of incomplete multipart uploads	Free	Cost optimization	Y	sum(IncompleteMultipartUploadStorageBytes) / sum(StorageBytes)	
Incomplete multipart upload object count	IncompleteMultipartUploadObjectCount	The number of objects in scope that are incomplete multipart uploads	Free	Cost optimization	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
% incomplete multipart upload objects	-	The percentage of objects in scope that are incomplete multipart uploads	Free	Cost optimization	Y	sum(IncompleteMultipartUploadObjectCount)/sum(ObjectCount)	
Incomplete multipart upload storage bytes greater than 7 days old	IncompleteMPUStorageBytesOlderThan7Days	The total bytes in scope for incomplete multipart uploads that are more than 7 days old	Free	Cost optimization	N	-	
% incomplete multipart upload storage bytes greater than 7 days old	-	The percentage of bytes for incomplete multipart uploads that are more than 7 days old	Free	Cost optimization	Y	sum(IncompleteMPUStorageBytesOlderThan7Days)/sum(StorageBytes)	
Incomplete multipart upload object count greater than 7 days old	IncompleteMPUObjectCountOlderThan7Days	The number of objects that are incomplete multipart uploads more than 7 days old	Free	Cost optimization	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
% incomplete multipart upload object count greater than 7 days old	-	The percentage of objects that are incomplete multipart uploads more than 7 days old	Free	Cost optimization	Y	sum(IncompleteMPUObjectCountOlderThan7Days)/sum(ObjectCount)	
Transition lifecycle rule count	TransitionLifecycleRuleCount	The count of lifecycle rules to transition objects to another storage class	Advanced	Cost optimization	N	-	
Average transition lifecycle rules per bucket	-	The average number of lifecycle rules to transition objects to another storage class	Advanced	Cost optimization	Y	sum(TransitionLifecycleRuleCount)/sum(DistinctNumberOfBuckets)	
Expiration lifecycle rule count	ExpirationLifecycleRuleCount	The count of lifecycle rules to expire objects	Advanced	Cost optimization	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derived metric form
Average expiration lifecycle rules per bucket	-	The average number of lifecycle rules to expire objects	Advanced optimization	Cost optimization	Y	sum(ExpirationLifecycleRuleCount)/sum(DistinctNumberOfBuckets)
Noncurrent version transition lifecycle rule count	NoncurrentVersionTransitionLifecycleRuleCount	The count of lifecycle rules to transition noncurrent object versions to another storage class	Advanced optimization	Cost optimization	N	
Average noncurrent version transition lifecycle rules per bucket	-	The average number of lifecycle rules to transition noncurrent object versions to another storage class	Advanced optimization	Cost optimization	Y	sum(NoncurrentVersionTransitionLifecycleRuleCount)/sum(DistinctNumberOfBuckets)
Noncurrent version expiration lifecycle rule count	NoncurrentVersionExpirationLifecycleRuleCount	The count of lifecycle rules to expire noncurrent object versions	Advanced optimization	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
Average noncurrent expiration lifecycle rules per bucket	-	The average number of lifecycle rules to expire noncurrent object versions	Advanced	Cost optimization	Y	sum(NoncurrentVersionExpirationLifecycleRuleCount)/sum(Distinct NumberOfBuckets)
Abort incomplete multipart upload lifecycle rule count	AbortIncompleteMPULifecycleRuleCount	The count of lifecycle rules to delete incomplete multipart uploads	Advanced	Cost optimization	N	-
Average abort incomplete multipart upload lifecycle rules per bucket	-	The average number of lifecycle rules to delete incomplete multipart uploads	Advanced	Cost optimization	Y	sum(AbortIncompleteMPULifecycleRuleCount)/sum(Distinct NumberOfBuckets)
Expired object delete marker lifecycle rule count	ExpiredObjectDeleteMarkerLifecycleRuleCount	The count of lifecycle rules to remove expired object delete markers	Advanced	Cost optimization	N	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average expired object delete marker lifecycle rules per bucket	-	The average number of lifecycle rules to remove expired object delete markers	Advanced	Cost optimization	Y	sum(ExpiredObjectDeleteMarkerLifecycleRuleCount)/sum(DistinctNumberOfWorkers)	
Total lifecycle rule count	TotalLifecycleRuleCount	The total count of lifecycle rules	Advanced	Cost optimization	N	-	
Average lifecycle rule count per bucket	-	The average number of lifecycle rules	Advanced	Cost optimization	Y	sum(TotalLifecycleRuleCount)/sum(DistinctNumberOfWorkers)	
Encrypted bytes	EncryptedStorageBytes	The total number of encrypted bytes	Free	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% encrypted bytes	-	The percentage of total bytes that are encrypted	Free	Data protection	Y	sum(EncryptedObjectCount)/sum(StorageBytes)	
Encrypted object count	Encrypted ObjectCount	The total count of objects that are encrypted	Free	Data protection	N	-	
% encrypted objects	-	The percentage of objects that are encrypted	Free	Data protection	Y	sum(EncryptedStorageBytes)/sum(ObjectCount)	
Unencrypted bytes	UnencryptedStorageBytes	The number of bytes that are unencrypted	Free	Data protection	Y	sum(StorageBytes) - sum(EncryptedStorageBytes)	
% unencrypted bytes	-	The percentage of bytes that are unencrypted	Free	Data protection	Y	sum(UnencryptedStorageBytes)/sum(StorageBytes)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Unencrypted object count	UnencryptedObjectCount	The total count of objects that are unencrypted	Free	Data protection	Y	sum(ObjectCount)	- sum(EncryptedObjectCount)
% unencrypted objects	-	The percentage of unencrypted objects	Free	Data protection	Y	sum(UnencryptedStorageBytes) / sum(ObjectCount)	-
Replicated storage bytes source	ReplicatedStorageBytesSource	The total number of bytes that are replicated from the source bucket	Free	Data protection	N	-	-
% replicated bytes source	-	The percentage of total bytes that are replicated from the source bucket	Free	Data protection	Y	sum(ReplicatedStorageBytesSource) / sum(StorageBytes)	-
Replicated object count source	ReplicatedObjectCountSource	The count of replicated objects from the source bucket	Free	Data protection	N	-	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
% replicated objects source	-	The percentage of total objects that are replicated from the source bucket	Free	Data protection	Y	sum(ReplicatedStorageObjectCount) / sum(ObjectCount)	
Replication storage bytes destination	Replicate dStorageBytes	The total number of bytes that are replicated to the destination bucket	Free	Data protection	Y	-	
% replicated bytes destination	-	The percentage of total bytes that are replicated to the destination bucket	Free	Data protection	Y	sum(ReplicatedStorageBytes) / sum(StorageBytes)	
Replicated object count destination	Replicate dObjectCount	The count of objects that are replicated to the destination bucket	Free	Data protection	Y	-	
% replicated objects destination	-	The percentage of total objects that are replicated to the destination bucket	Free	Data protection	Y	sum(ReplicatedObjectCount) / sum(ObjectCount)

Versioning-enabled bucket count	VersioningEnabledBucketCount	The count of buckets that have S3 Versioning enabled	Free	Data protection	N	-	
% versioning-enabled buckets	-	The percentage of buckets that have S3 Versioning enabled	Free	Data protection	Y	sum(VersioningEnabledBucketCount)/sum(DistinctNumberOfBuckets)	
MFA delete-enabled bucket count	MFADeleteEnabledBucketCount	The count of buckets that have MFA (multi-factor authentication) delete enabled	Free	Data protection	N	-	
% MFA delete-enabled buckets	-	The percentage of buckets that have MFA (multi-factor authentication) delete enabled	Free	Data protection	Y	sum(MFADeleteEnabledBucketCount)/sum(DistinctNumberOfBuckets)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
SSE-KMS enabled bucket count	SSEKMSEnabledBucketCount	The count of buckets that use server-side encryption with AWS Key Management Service keys (SSE-KMS) for default bucket encryption	Free	Data protection	N	-	
% SSE-KMS enabled buckets	-	The percentage of buckets that SSE-KMS for default bucket encryption	Free	Data protection	Y	sum(SSEKMSEnabledBucketCount) / sum(DistinctNumberOfBuckets)	
All unsupported signature requests	AllUnsupportedSignatureRequests	The total number of requests that use unsupported AWS signature versions	Advanced protection	Data protection	N	-	
% all unsupported signature requests	-	The percentage of requests that use unsupported AWS signature versions	Advanced protection	Data protection	Y	sum(AllUnsupportedSignatureRequests) / sum(AllRequests)	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
All unsupported TLS requests	AllUnsupportedTLSRequests	The number of requests that use unsupported Transport Layer Security (TLS) versions	Advanced	Data protection	No	-	
% all unsupported TLS requests	-	The percentage of requests that use unsupported TLS versions	Advanced	Data protection	Yes	$\text{sum}(\text{AllUnsupportedTLSRequests}) / \text{sum}(\text{AllRequests})$	
All SSE-KMS requests	AllSSEKMSRequests	The total number of requests that specify SSE-KMS	Advanced	Data protection	No	-	
% all SSE-KMS requests	-	The percentage of requests that specify SSE-KMS	Advanced	Data protection	Yes	$\text{sum}(\text{AllSSEKMSRequests}) / \text{sum}(\text{AllRequests})$	
Same-Region Replication rule count	SameRegionReplicationRuleCount	The count of replication rules for Same-Region Replication (SRR)	Advanced	Data protection	No	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Average Same-Region Replication rules per bucket	-	The average number of replication rules for SRR	Advanced	Data protection	Y	sum(SameRegionReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Cross-Region Replication rule count	CrossRegionReplicationRuleCount	The count of replication rules for Cross-Region Replication (CRR)	Advanced	Data protection	N	-	
Average Cross-Region Replication rules per bucket	-	The average number of replication rules for CRR	Advanced	Data protection	Y	sum(CrossRegionReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Same-account replication rule count	SameAccountReplicationRuleCount	The count of replication rules for replication within the same account	Advanced	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average same-account replication rules per bucket	-	The average number of replication rules for replication within the same account	Advanced	Data protection	Y	sum(SameAccountReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Cross-account replication rule count	CrossAccountReplicationRuleCount	The count of replication rules for cross-account replication	Advanced	Data protection	N	-	
Average cross-account replication rules per bucket	-	The average number of replication rules for cross-account replication	Advanced	Data protection	Y	sum(CrossAccountReplicationRuleCount) / sum(DistinctNumberOfBuckets)	
Invalid destination replication rule count	InvalidDestinationReplicationRuleCount	The count of replication rules with a replication destination that's not valid	Advanced	Data protection	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Average invalid destination replication rules per bucket	-	The average number of replication rules with a replication destination that's not valid	Advanced protection	Data protection	Y	sum(InvalidReplicaCount)/sum(DistinctNumberOfBuckets)	
Total replication rule count	-	The total replication rule count	Advanced protection	Data protection	Y	-	
Average replication rule count per bucket	-	The average total replication rule count	Advanced protection	Data protection	Y	sum(all replication rule count metrics)/sum(DistinctNumberOfBuckets)	
Object Ownership bucket owner enforced bucket count	ObjectOwnershipBucketOwnerEnforcedBucketCount	The total count of buckets that have access control lists (ACLs) disabled by using the bucket owner enforced setting for Object Ownership	Free	Access management	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derived metric	Definition
% Object Ownership bucket owner enforced buckets	-	The percentage of buckets that have ACLs disabled by using the bucket owner enforced setting for Object Ownership	Free	Access management	Y	sum(ObjectOwnershipBucketOwnerEnforcedBucketCount) / sum(DistinctNumberOfBuckets)	sum(DistinctNumberOfBuckets)
Object Ownership bucket owner preferred bucket count	ObjectOwnershipBucketOwnerPreferredBucketCount	The total count of buckets that use the bucket owner preferred setting for Object Ownership	Free	Access management	N	-	-
% Object Ownership bucket owner preferred buckets	-	The percentage of buckets that use the bucket owner preferred setting for Object Ownership	Free	Access management	Y	sum(ObjectOwnershipBucketOwnerPreferredBucketCount) / sum(DistinctNumberOfBuckets)	sum(DistinctNumberOfBuckets)

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
Object Ownership object writer bucket count	ObjectOwnershipObj ectWriter BucketCount	The total count of buckets that use the object writer setting for Object Ownership	Free	Access management	No	-	
% Object Ownership object writer buckets	-	The percentage of buckets that use the object writer setting for Object Ownership	Free	Access management	Yes	$\text{sum(ObjectOwnershipObjectWriterBucketCount)}/\text{sum(DistinctNumberOfBuckets)}$	
Transfer Acceleration enabled bucket count	TransferAccelerationEnabled BucketCount	The total count of buckets that have Transfer Acceleration enabled	Free	Performance	No	-	
% Transfer Acceleration enabled buckets	-	The percentage of buckets that have Transfer Acceleration enabled	Free	Performance	Yes	$\text{sum(TransferAccelerationEnabledBucketCount)}/\text{sum(DistinctNumberOfBuckets)}$	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
Event Notification enabled bucket count	EventNotificationEnabledBucketCount	The total count of buckets that have Event Notifications enabled	Free	Ever	N		
% Event Notification enabled buckets	-	The percentage of buckets that have Event Notifications enabled	Free	Ever	Y	sum(EventNotificationEnabledBucketCount)/sum(DistinctNumberOfBuckets)	
All requests	AllRequests	The total number of requests made	Advanced	Active	N	-	
Get requests	GetRequests	The total number of GET requests made	Advanced	Active	N	-	
Put requests	PutRequests	The total number of PUT requests made	Advanced	Active	N	-	
Head requests	HeadRequests	The total number of HEAD requests made	Advanced	Active	N	-	
Delete requests	DeleteRequests	The total number of DELETE requests made	Advanced	Active	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric form
List requests	ListRequests	The total number of LIST requests made	Advanced	Activity	No	-

Select requests	SelectRequests	The total number of S3 Select requests	Advanced	Activity	No	-
Select scanned bytes	SelectScannedBytes	The number of S3 Select bytes scanned	Advanced	Activity	No	-
Select returned bytes	SelectReturnedBytes	The number of S3 Select bytes returned	Advanced	Activity	No	-
Bytes downloaded	BytesDownloaded	The number of bytes downloaded	Advanced	Activity	No	-
% retrieval rate	-	The percentage of bytes downloaded	Advanced	Activity	Yes	sum(BytesDownloaded)/sum(StorageBytes)
Bytes uploaded	BytesUploaded	The number of bytes uploaded	Advanced	Activity	No	-

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derivative metric	Form
% ingest ratio	-	The percentage of bytes uploaded	Advanced	Activity	Y	sum(Bytes Uploaded) / sum(StorageBytes)	
4xx errors	4xxErrors	The total number of HTTP 4xx status codes	Advanced	Activity	N	-	
5xx errors	5xxErrors	The total number of HTTP 5xx status codes	Advanced	Activity	N	-	
Total errors	-	The sum of all 4xx and 5xx errors	Advanced	Activity	Y	sum(4xxErrors) + sum(5xxErrors)	
% error rate	-	The total number of 4xx and 5xx errors as a percentage of total requests	Advanced	Activity	Y	sum(Total Errors) / sum(Total Requests)	
200 OK status count	200OKStatusCount	The total count of 200 OK status codes	Advanced	Detail status code	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Data type	Derivation metric	Form
% 200 OK status	-	The total number of 200 OK status codes as a percentage of total requests	Advanced	Detail status codes	Y	sum(200OKStatusCount)/sum(AllRequests)	
206 Partial Content status count	206PartialContentStatusCount	The total count of 206 Partial Content status codes	Advanced	Detail status codes	N	-	
% 206 Partial Content status	-	The total number of 206 Partial Content status codes as a percentage of total requests	Advanced	Detail status codes	Y	sum(206PartialContentStatusCount)/sum(AllRequests)	
400 Bad Request error count	400BadRequestErrorCount	The total count of 400 Bad Request status codes	Advanced	Detail status codes	N	-	
% 400 Bad Request errors	-	The total number of 400 Bad Request status codes as a percentage of total requests	Advanced	Detail status codes	Y	sum(400BadRequestErrorCount)/sum(AllRequests)	
403 Forbidden error count	403ForbiddenErrorCount	The total count of 403 Forbidden status codes	Advanced	Detail status codes	N	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimension	Derivative metric	Form
% 403 Forbidden errors	-	The total number of 403 Forbidden status codes as a percentage of total requests	Advanced	Detail status codes	Yes	sum(403ForbiddenErrorCount) / sum(AllRequests)	
404 Not Found error count	404NotFoundErrorCodeCount	The total count of 404 Not Found status codes	Advanced	Detail status codes	No	-	
% 404 Not Found errors	-	The total number of 404 Not Found status codes as a percentage of total requests	Advanced	Detail status codes	Yes	sum(404NotFoundErrorCodeCount) / sum(AllRequests)	
500 Internal Server Error count	500InternalServerErrorCount	The total count of 500 Internal Server Error status codes	Advanced	Detail status codes	No	-	
% 500 Internal Server Errors	-	The total number of 500 Internal Server Error status codes as a percentage of total requests	Advanced	Detail status codes	Yes	sum(500InternalServerErrorCount) / sum(AllRequests)	
503 Service Unavailable error count	503ServiceUnavailableErrorCodeCount	The total count of 503 Service Unavailable status codes	Advanced	Detail status codes	No	-	

Metric name	CloudWatch and export	Description	Tier ¹	Category	Dimensions	Derived metric	Form
% 503 Service Unavailable errors	-	The total number of 503 Service Unavailable status codes as a percentage of total requests	Advanced tier	Detail status code	Y	sum(503ServiceUnavailableErrorsCount) / sum(AllRequests)	

¹ All free tier storage metrics are available at the Storage Lens group level. Advanced tier metrics are not available at the Storage Lens group level.

² Rule count metrics and bucket settings metrics aren't available at the prefix level.

Setting Amazon S3 Storage Lens permissions

Amazon S3 Storage Lens requires new permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to enable or disable S3 Storage Lens, or to access any S3 Storage Lens dashboard or configuration.

The IAM user or role must belong to the account that created or owns the dashboard or configuration, unless both of the following conditions are true:

- Your account is a member of AWS Organizations.
- You were given access to create organization-level dashboards by your management account as a delegated administrator.

Note

- You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required IAM

permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Security best practices in IAM in the IAM User Guide](#).

- Using S3 Storage Lens on the Amazon S3 console can require multiple permissions. For example, to edit a dashboard on the console, you need the following permissions:
 - `s3>ListStorageLensConfigurations`
 - `s3:GetStorageLensConfiguration`
 - `s3:PutStorageLensConfiguration`

Topics

- [Setting account permissions to use S3 Storage Lens](#)
- [Setting account permissions to use S3 Storage Lens groups](#)
- [Setting permissions to use S3 Storage Lens with AWS Organizations](#)

Setting account permissions to use S3 Storage Lens

To create and manage S3 Storage Lens dashboards and Storage Lens dashboard configurations, you must have the following permissions, depending on which actions you want to perform:

The following table shows Amazon S3 Storage Lens related IAM permissions.

Action	IAM permissions
Create or update an S3 Storage Lens dashboard in the Amazon S3 console.	<code>s3>ListStorageLensConfigurations</code> <code>s3:GetStorageLensConfiguration</code> <code>s3:GetStorageLensConfigurationTagging</code> <code>s3:PutStorageLensConfiguration</code> <code>s3:PutStorageLensConfigurationTagging</code>

Action	IAM permissions
Get the tags of an S3 Storage Lens dashboard on the Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfigurationTagging
View an S3 Storage Lens dashboard on the Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfiguration s3:GetStorageLensDashboard
Delete an S3 Storage Lens dashboard on Amazon S3 console.	s3>ListStorageLensConfigurations s3:GetStorageLensConfiguration s3>DeleteStorageLensConfiguration
Create or update an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3>PutStorageLensConfiguration s3>PutStorageLensConfigurationTagging
Get the tags of an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3>GetStorageLensConfigurationTagging
View an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	s3>GetStorageLensConfiguration
Delete an S3 Storage Lens configuration by using the AWS CLI or AWS SDK.	s3>DeleteStorageLensConfiguration

Note

- You can use resource tags in an IAM policy to manage permissions.
- An IAM user or role with these permissions can see metrics from buckets and prefixes that they might not have direct permission to read or list objects from.

- For S3 Storage Lens dashboards with prefix-level metrics enabled, if a selected prefix path matches with an object key, the dashboard might display the object key as another prefix.
- For metrics exports, which are stored in a bucket in your account, permissions are granted by using the existing `s3:GetObject` permission in the IAM policy. Similarly, for an AWS Organizations entity, the organization's management account or delegated administrator accounts can use IAM policies to manage access permissions for organization-level dashboard and configurations.

Setting account permissions to use S3 Storage Lens groups

You can use S3 Storage Lens groups to understand the distribution of your storage within buckets based on prefix, suffix, object tag, object size, or object age. You can attach Storage Lens groups to your dashboards to view their aggregated metrics.

To work with Storage Lens groups, you need certain permissions. For more information, see [the section called "Storage Lens groups permissions".](#)

Setting permissions to use S3 Storage Lens with AWS Organizations

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. The following table shows the actions and permissions related to using S3 Storage Lens with Organizations.

Action	IAM Permissions
Enable trusted access for S3 Storage Lens for your organization.	<code>organizations:EnableAWSServiceAccess</code>
Disable trusted access for S3 Storage Lens for your organization.	<code>organizations:DisableAWSServiceAccess</code>
Register a delegated administrator to create S3 Storage Lens dashboards or configurations for your organization.	<code>organizations:RegisterDelegatedAdministrator</code>

Action	IAM Permissions
Deregister a delegated administrator so that they can no longer create S3 Storage Lens dashboards or configurations for your organization.	organizations:DeregisterDelegatedAdministrator
Additional permissions to create S3 Storage Lens organization-wide configurations.	organizations:DescribeOrganization organizations>ListAccounts organizations>ListAWSServiceAccessForOrganization organizations>ListDelegatedAdministrators iam>CreateServiceLinkedRole

Working with Amazon S3 Storage Lens by using the console and API

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your

dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The following sections contain examples of creating, updating, and viewing S3 Storage Lens configurations and performing operations related to the feature. If you are using S3 Storage Lens with AWS Organizations, these examples also cover those use cases. In the examples, replace any variable values with those that are specific to you.

Create an Amazon S3 Storage Lens dashboard

You can create additional S3 Storage Lens custom dashboards that can be scoped to your organization in AWS Organizations or to specific AWS Regions or buckets within an account.

Note

Any updates to your dashboard configuration can take up to 48 hours to accurately display or visualize.

Using the S3 console

Use the following steps to create an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Define the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, under **S3 Storage Lens**, choose **Dashboards**.
4. Choose **Create dashboard**.
5. On the **Dashboard** page, in the **General** section, do the following:
 - a. View the **Home Region** for your dashboard. The home Region is the AWS Region where the configuration and metrics for this Storage Lens dashboard are stored.
 - b. Enter a dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces.

 **Note**

You can't change this dashboard name after the dashboard is created.

- c. You can optionally choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens.

For more information, see [Controlling access using resource tags](#) in the *IAM User Guide* and [AWS-Generated Cost Allocation Tags](#) in the *AWS Billing User Guide*.

 **Note**

You can add up to 50 tags to your dashboard configuration.

6. In the **Dashboard scope** section, do the following:
 - a. Choose the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.
 - b. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not available when you create organization-level dashboards.

Note

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

Step 2: Configure the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.
 - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
 - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:
 - **Advanced metrics**
 - **CloudWatch publishing**
 - **Prefix aggregation**

⚠ Important

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

4. If you chose to enable prefix aggregation, configure the following:

- a. Choose the minimum prefix threshold size for this dashboard.

For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

- b. Choose the prefix depth.

This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

- c. Enter a prefix delimiter character.

This value is used to identify each prefix level. The default value in Amazon S3 is the / character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**.

The metrics export is in CSV or Apache Parquet format. It represents the same scope of data as your S3 Storage Lens dashboard data without the recommendations.

2. If you enabled the metrics export, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.

You can choose a bucket in the current account of the S3 Storage Lens dashboard. Or you can choose another AWS account if you have the destination bucket permissions and the destination bucket owner's account ID.

4. Choose the destination S3 bucket (format: s3://*bucket-name/prefix*).

The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type: Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

You can choose between an [Amazon S3 managed key \(SSE-S3\)](#) and an [AWS Key Management Service \(AWS KMS\) key \(SSE-KMS\)](#).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN).

If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

7. Choose **Create dashboard**.

Using the AWS CLI

Example

The following example command creates a Amazon S3 Storage Lens configuration with tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --  
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-  
configuration=file://./config.json --tags=file://./tags.json
```

Example

The following example command creates a Amazon S3 Storage Lens configuration without tags. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json
```

Using the AWS SDK for Java

Example – Create and update an Amazon S3 Storage Lens configuration

The following example creates and updates an Amazon S3 Storage Lens configuration in SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.ActivityMetrics;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.CloudWatchMetrics;
import com.amazonaws.services.s3control.model.Format;
import com.amazonaws.services.s3control.model.Include;
import com.amazonaws.services.s3control.model.OutputSchemaVersion;
import com.amazonaws.services.s3control.model.PrefixLevel;
import com.amazonaws.services.s3control.model.PrefixLevelStorageMetrics;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.S3BucketDestination;
import com.amazonaws.services.s3control.model.SSES3;
import com.amazonaws.services.s3control.model.SelectionCriteria;
import com.amazonaws.services.s3control.model.StorageLensAwsOrg;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensDataExport;
import com.amazonaws.services.s3control.model.StorageLensDataExportEncryption;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
```

```
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateAndUpdateDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        String exportAccountId = "Destination Account ID";
        String exportBucketArn = "arn:aws:s3:::destBucketName"; // The destination
bucket for your metrics export must be in the same Region as your S3 Storage Lens
configuration.
        String awsOrgARN = "arn:aws:organizations::123456789012:organization/o-
abcdefg";
        Format exportFormat = Format.CSV;

        try {
            SelectionCriteria selectionCriteria = new SelectionCriteria()
                .withDelimiter("/")
                .withMaxDepth(5)
                .withMinStorageBytesPercentage(10.0);
            PrefixLevelStorageMetrics prefixStorageMetrics = new
PrefixLevelStorageMetrics()
                .withEnabled(true)
                .withSelectionCriteria(selectionCriteria);
            BucketLevel bucketLevel = new BucketLevel()

AdvancedCostOptimizationMetrics().withEnabled(true))
                .withAdvancedDataProtectionMetrics(new
AdvancedDataProtectionMetrics().withEnabled(true))
                .withDetailedStatusCodesMetrics(new
DetailedStatusCodesMetrics().withEnabled(true))
                .withPrefixLevel(new
PrefixLevel().withStorageMetrics(prefixStorageMetrics));
            AccountLevel accountLevel = new AccountLevel()
                .withActivityMetrics(new ActivityMetrics().withEnabled(true))
                .withAdvancedCostOptimizationMetrics(new
AdvancedCostOptimizationMetrics().withEnabled(true))
                .withAdvancedDataProtectionMetrics(new
AdvancedDataProtectionMetrics().withEnabled(true))
                .withDetailedStatusCodesMetrics(new
DetailedStatusCodesMetrics().withEnabled(true))
        
```

```
.withBucketLevel(bucketLevel);

Include include = new Include()
    .withBuckets(Arrays.asList("arn:aws:s3:::bucketName"))
    .withRegions(Arrays.asList("us-west-2"));

StorageLensDataExportEncryption exportEncryption = new
StorageLensDataExportEncryption()
    .withSSES3(new SSES3());
S3BucketDestination s3BucketDestination = new S3BucketDestination()
    .withAccountId(exportAccountId)
    .withArn(exportBucketArn)
    .withEncryption(exportEncryption)
    .withFormat(exportFormat)
    .withOutputSchemaVersion(OutputSchemaVersion.V_1)
    .withPrefix("Prefix");
CloudWatchMetrics cloudWatchMetrics = new CloudWatchMetrics()
    .withEnabled(true);
StorageLensDataExport dataExport = new StorageLensDataExport()
    .withCloudWatchMetrics(cloudWatchMetrics)
    .withS3BucketDestination(s3BucketDestination);

StorageLensAwsOrg awsOrg = new StorageLensAwsOrg()
    .withArn(awsOrgARN);

StorageLensConfiguration configuration = new StorageLensConfiguration()
    .withId(configurationId)
    .withAccountLevel(accountLevel)
    .withInclude(include)
    .withDataExport(dataExport)
    .withAwsOrg(awsOrg)
    .withEnabled(true);

List<StorageLensTag> tags = Arrays.asList(
    new StorageLensTag().withKey("key-1").withValue("value-1"),
    new StorageLensTag().withKey("key-2").withValue("value-2")
);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();
```

```
s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
    .withTags(tags)
);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see [the section called “Working with Storage Lens groups”](#).

Update an Amazon S3 Storage Lens dashboard

The Amazon S3 Storage Lens default dashboard is `default-account-dashboard`. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export,

or even disable the default dashboard. The default dashboard can't be deleted, and can only be disabled. For more information, see [Using the S3 console](#).

Using the S3 console

Use the following steps to update an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Update the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.

The **Edit dashboard** page opens.

Note

You can't change the following:

- The dashboard name
- The home Region
- The dashboard scope of the default dashboard, which is scoped to your entire account's storage

4. (Optional) On the dashboard configuration page, in the **General** section, update and add tags to your dashboard.

You can use tags to manage permissions for your dashboard and to track costs for S3 Storage Lens. For more information, see [Controlling access using resource tags](#) in the *IAM User Guide* and [AWS-Generated Cost Allocation Tags](#) in the *AWS Billing User Guide*.

Note

You can add up to 50 tags to your dashboard configuration.

5. In the **Dashboard scope** section, do the following:

- a. Update the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

 **Note**

- You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
- You can choose up to 50 buckets to include or exclude.

- b. Update the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not present when creating organization-level dashboards.

Step 2: Update the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.
 - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
 - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see [Amazon S3 pricing](#).

For more information about advanced metrics and free metrics, see [Metrics selection](#).

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:
 - **Advanced metrics**
 - **CloudWatch publishing**
 - **Prefix aggregation**

⚠️ Important

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

4. If you chose to enable prefix aggregation, configure the following:

- a. Choose the minimum prefix threshold size for this dashboard.

For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

- b. Choose the prefix depth.

This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

- c. Enter a prefix delimiter character.

This is the value used to identify each prefix level. The default value in Amazon S3 is the / character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**. To disable the metrics export, choose **Disable**.

The metrics export is in CSV or Apache Parquet format. It represents the same scope of data as your S3 Storage Lens dashboard data without the recommendations.

2. If enabled, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.

You can choose a bucket in the current account of the S3 Storage Lens dashboard. Or you can choose another AWS account if you have the destination bucket permissions and the destination bucket owner's account ID.

4. Choose the destination S3 bucket (format: s3://*bucket-name/prefix*).

The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type**: **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

You can choose between an [Amazon S3 managed key](#) (SSE-S3) and an [AWS Key Management Service \(AWS KMS\)](#) key (SSE-KMS).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN). Under **AWS KMS key**, specify your KMS key in one of the following ways:

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

Both the AWS managed key (aws/s3) and your customer managed keys appear in this list. For more information about customer managed keys, see [Customer keys and AWS keys](#) in the *AWS Key Management Service Developer Guide*.

 **Note**

The AWS managed key (aws/S3) is not supported for SSE-KMS encryption with S3 Storage Lens.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see [Using an AWS KMS key to encrypt your metrics exports](#).

For more information about creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.

7. Choose **Save changes**.

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see [the section called “Working with Storage Lens groups”](#).

Using the AWS CLI

Example

The following example command updates a Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --  
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-  
configuration=file://./config.json --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Update a Amazon S3 Storage Lens configuration with advanced metrics and recommendations

The following examples shows you how to update the default S3 Storage Lens configuration with advanced metrics and recommendations in SDK for Java:

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.services.s3control.AWSS3Control;  
import com.amazonaws.services.s3control.AWS3ControlClient;  
import com.amazonaws.services.s3control.model.AccountLevel;  
import com.amazonaws.services.s3control.model.ActivityMetrics;  
import com.amazonaws.services.s3control.model.BucketLevel;  
import com.amazonaws.services.s3control.model.Format;  
import com.amazonaws.services.s3control.model.Include;  
import com.amazonaws.services.s3control.model.OutputSchemaVersion;  
import com.amazonaws.services.s3control.model.PrefixLevel;  
import com.amazonaws.services.s3control.model.PrefixLevelStorageMetrics;  
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;  
import com.amazonaws.services.s3control.model.S3BucketDestination;  
import com.amazonaws.services.s3control.model.SSES3;  
import com.amazonaws.services.s3control.model.SelectionCriteria;  
import com.amazonaws.services.s3control.model.StorageLensAwsOrg;  
import com.amazonaws.services.s3control.model.StorageLensConfiguration;  
import com.amazonaws.services.s3control.model.StorageLensDataExport;  
import com.amazonaws.services.s3control.model.StorageLensDataExportEncryption;  
import com.amazonaws.services.s3control.model.StorageLensTag;
```

```
import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class UpdateDefaultConfigWithPaidFeatures {

    public static void main(String[] args) {
        String configurationId = "default-account-dashboard"; // This configuration ID
        cannot be modified.
        String sourceAccountId = "111122223333";

        try {
            SelectionCriteria selectionCriteria = new SelectionCriteria()
                .withDelimiter("/")
                .withMaxDepth(5)
                .withMinStorageBytesPercentage(10.0);
            PrefixLevelStorageMetrics prefixStorageMetrics = new
            PrefixLevelStorageMetrics()
                .withEnabled(true)
                .withSelectionCriteria(selectionCriteria);
            BucketLevel bucketLevel = new BucketLevel()
                .withActivityMetrics(new ActivityMetrics().withEnabled(true))
                .withPrefixLevel(new
            PrefixLevel().withStorageMetrics(prefixStorageMetrics));
            AccountLevel accountLevel = new AccountLevel()
                .withActivityMetrics(new ActivityMetrics().withEnabled(true))
                .withBucketLevel(bucketLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
                .withAccountLevel(accountLevel)
                .withEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfiguration(new
            PutStorageLensConfigurationRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
        }
    }
}
```

```
        .withStorageLensConfiguration(configuration)
    );

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Note

Additional charges apply for advanced metrics and recommendations. For more information, see [advanced metrics and recommendations](#).

Disable an Amazon S3 Storage Lens dashboard

You can disable an Amazon S3 Storage Lens dashboard from the Amazon S3 console. Disabling a dashboard prevents it from generating metrics in the future. A disabled dashboard still retains its configuration information, so that it can be easily resumed when re-enabled. A disabled dashboard retains its historical data until it's no longer available for queries.

Using the S3 console

Use the following steps to disable an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

To disable an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to disable, and then choose **Disable** at the top of the list.

4. On the confirmation page, confirm that you want to disable the dashboard by entering the name of dashboard in the text field, and then choose **Confirm**.

Delete an Amazon S3 Storage Lens dashboard

You can't delete the default dashboard. However, you can disable it. Before deleting a dashboard that you've created, consider the following:

- As an alternative to deleting a dashboard, you can *disable* the dashboard so that it is available to be re-enabled in the future. For more information, see [Using the S3 console](#).
- Deleting the dashboard deletes all the configuration settings that are associated with it.
- Deleting a dashboard makes all the historic metrics data unavailable. This historical data is still retained for 15 months. If you want to access this data again, create a dashboard with the same name in the same home Region as the one that was deleted.

Using the S3 console

You can delete an Amazon S3 Storage Lens dashboard from the Amazon S3 console. However, deleting a dashboard prevents it from generating metrics in the future.

Deleting an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to delete, and then choose **Delete** at the top of the list.
4. On the **Delete dashboards** page, confirm that you want to delete the dashboard by entering the name of dashboard in the text field. Then choose **Confirm**.

Using the AWS CLI

Example

The following example deletes a S3 Storage Lens configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-configuration --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

Example – Delete an Amazon S3 Storage Lens dashboard configuration

The following example shows you how to delete an S3 Storage Lens configuration using SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.deleteStorageLensConfiguration(new
DeleteStorageLensConfigurationRequest()

        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
        }
    }
}
```

```
// couldn't parse the response from Amazon S3.  
e.printStackTrace();  
}  
}  
}
```

List Amazon S3 Storage Lens dashboards

Using the S3 console

To list S3 Storage Lens dashboards

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**. You can now view the dashboards in your AWS account.

Using the AWS CLI

Example

The following example command lists the S3 Storage Lens dashboards in your AWS account. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1 --next-token=abcdefghijklm1234
```

Example

The following example lists S3 Storage Lens configurations without a next token. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1
```

Using the AWS SDK for Java

Example – List S3 Storage Lens dashboard configurations

The following examples shows you how to list S3 Storage Lens configurations in SDK for Java. To use this example, replace the *user input placeholders* with your own information." to each example description.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationEntry;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationsRequest;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class ListDashboard {

    public static void main(String[] args) {
        String sourceAccountId = "111122223333";
        String nextToken = "nextToken";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            final List<ListStorageLensConfigurationEntry> configurations =
                s3ControlClient.listStorageLensConfigurations(new
                    ListStorageLensConfigurationsRequest()
                        .withAccountId(sourceAccountId)
                        .withNextToken(nextToken)
                ).getStorageLensConfigurationList();

            System.out.println(configurations.toString());
        } catch (AmazonServiceException e) {
    
```

```
// The call was transmitted successfully, but Amazon S3 couldn't process
// it and returned an error response.
e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

View an Amazon S3 Storage Lens dashboard configuration details

You can view a Amazon S3 Storage Lens dashboard from the Amazon S3 console, AWS CLI, and SDK for Java.

Using the S3 console

To view S3 Storage Lens dashboard configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. From the **Dashboards** list, click on the dashboard that you want to view. You can now view the details of your Storage Lens dashboard.

Using the AWS CLI

Example

The following example retrieves an S3 Storage Lens configuration so that you can view the configuration details. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration --account-id=222222222222 --config-
id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

Example – Retrieve and view an S3 Storage Lens configuration

The following example shows you how to retrieve an S3 Storage Lens configuration in SDK for Java so that you can view the configuration details. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationResult;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            final StorageLensConfiguration configuration =
                s3ControlClient.getStorageLensConfiguration(new
GetStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .getStorageLensConfiguration());

            System.out.println(configuration.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
        }
    }
}
```

```
        // it and returned an error response.  
        e.printStackTrace();  
    } catch (SdkClientException e) {  
        // Amazon S3 couldn't be contacted for a response, or the client  
        // couldn't parse the response from Amazon S3.  
        e.printStackTrace();  
    }  
}  
}
```

Managing AWS resource tags with S3 Storage Lens

Each Amazon S3 Storage Lens dashboard is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens dashboard, you can optionally add AWS resource tags to the dashboard. You can add up to 50 tags for each Storage Lens dashboard. To create a Storage Lens dashboard with tags, you must have the following [S3 Storage Lens permissions](#):

- s3>ListStorageLensConfigurations
- s3:GetStorageLensConfiguration
- s3:GetStorageLensConfigurationTagging
- s3:PutStorageLensConfiguration
- s3:PutStorageLensConfigurationTagging

You can use AWS resource tags to categorize resources according to department, line of business, or project. This is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific S3 Storage Lens dashboard based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens dashboard, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes such as tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.

- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with aws :) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens dashboard.

Add AWS resource tags to a Storage Lens dashboard

The following examples demonstrate how to add AWS resource tags to an S3 Storage Lens dashboard. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add AWS resource tags to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens** on the left navigation panel.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard that you want to update. Then, choose **Edit**.
5. Under **General**, choose **Add tag**.
6. On the **Add tag** page, add the new key-value pair.

Note

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens dashboard.
8. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
9. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds tags to a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

The following example adds tags to an Amazon S3 Storage Lens configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

Example – Add tags to an S3 Storage Lens configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
```

```
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                new StorageLensTag().withKey("key-1").withValue("value-1"),
                new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
PutStorageLensConfigurationTaggingRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Retrieve AWS resource tags for a Storage Lens dashboard

The following examples demonstrate how to retrieve AWS resource tags for a S3 Storage Lens dashboard. You can get resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To retrieve the AWS resource tags for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command retrieves tags for a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration-tagging --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Get tags for an S3 Storage Lens dashboard configuration

The following example shows you how to retrieve tags for an S3 Storage Lens dashboard configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;
import
com.amazonaws.services.s3control.model.GetStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            final List<StorageLensTag> s3Tags = s3ControlClient
                .getStorageLensConfigurationTagging(new
GetStorageLensConfigurationTaggingRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
            ).getTags();

            System.out.println(s3Tags.toString());
        }
    }
}
```

```
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Updating Storage Lens dashboard tags

The following examples demonstrate how to update Storage Lens dashboard tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds or replaces tags on an existing Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=111122223333 --config-id=example-dashboard-configuration-id --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates the AWS resource tags on an existing Storage Lens dashboard. To use this example, replace the *user input placeholders* with your own information.

Example – Update tags on an existing Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
```

```
        List<StorageLensTag> tags = Arrays.asList(
            new StorageLensTag().withKey("key-1").withValue("value-1"),
            new StorageLensTag().withKey("key-2").withValue("value-2"))
        );

        AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(US_WEST_2)
            .build();

        s3ControlClient.putStorageLensConfigurationTagging(new
PutStorageLensConfigurationTaggingRequest()
            .withAccountId(sourceAccountId)
            .withConfigId(configurationId)
            .withTags(tags)
        );
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

Deleting AWS resource tags from a S3 Storage Lens dashboard

The following examples demonstrate how to delete AWS resource tags from an existing Storage Lens dashboard. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete AWS resource tags from an existing Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.

4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. Choose **Remove** next to the tag that you want to remove.
7. Choose **Save changes**.

Using the AWS CLI

The following AWS CLI command deletes AWS resource tags from an existing Storage Lens dashboard. To use this example command, replace the *user input placeholders* with your own information.

Example

```
aws s3control delete-storage-lens-configuration-tagging --account-id=222222222222 --config-id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes an AWS resource tag from the Storage Lens dashboard using the Amazon Resource Name (ARN) that you specify in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

Example – Delete tags for an S3 Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationTaggingRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
```

```
String sourceAccountId = "111122223333";
try {
    AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
        .withCredentials(new ProfileCredentialsProvider())
        .withRegion(US_WEST_2)
        .build();

    s3ControlClient.deleteStorageLensConfigurationTagging(new
DeleteStorageLensConfigurationTaggingRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Helper files for using Amazon S3 Storage Lens

Use the following JSON files and its key inputs for your examples.

S3 Storage Lens example configuration in JSON

Example config.json

The config.json file contains the details of a S3 Storage Lens Organizations-level *advanced metrics and recommendations* configuration. To use the following example, replace the *user input placeholders* with your own information.

Note

Additional charges apply for advanced metrics and recommendations. For more information, see [advanced metrics and recommendations](#).

```
{  
    "Id": "SampleS3StorageLensConfiguration", //Use this property to identify your S3  
    Storage Lens configuration.  
    "AwsOrg": { //Use this property when enabling S3 Storage Lens for AWS Organizations.  
        "Arn": "arn:aws:organizations::123456789012:organization/o-abcdefg"  
    },

```

S3 Storage Lens example configuration with Storage Lens groups in JSON

Example config.json

The config.json file contains the details that you want to apply to your Storage Lens configuration when using Storage Lens groups. To use the example, replace the *user input placeholders* with your own information.

To attach all Storage Lens groups to your dashboard, update your Storage Lens configuration with the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
```

```
"AccountLevel": {  
    "ActivityMetrics": {  
        "Enabled": true  
    },  
    "AdvancedCostOptimizationMetrics": {  
        "Enabled": true  
    },  
    "AdvancedDataProtectionMetrics": {  
        "Enabled": true  
    },  
    "BucketLevel": {  
        "ActivityMetrics": {  
            "Enabled": true  
        },  
        "StorageLensGroupLevel": {},  
        "Enabled": true  
    }  
}
```

To include only two Storage Lens groups in your Storage Lens dashboard configuration (*slg-1* and *slg-2*), use the following syntax:

```
{  
    "Id": "ExampleS3StorageLensConfiguration",  
    "AccountLevel": {  
        "ActivityMetrics": {  
            "Enabled": true  
        },  
        "AdvancedCostOptimizationMetrics": {  
            "Enabled": true  
        },  
        "AdvancedDataProtectionMetrics": {  
            "Enabled": true  
        },  
        "BucketLevel": {  
            "ActivityMetrics": {  
                "Enabled": true  
            },  
            "StorageLensGroupLevel": {  
                "SelectionCriteria": {  
                    "Include": [  
                        "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slgroup-1",  
                        "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slgroup-2"  
                    ]  
                }  
            }  
        }  
    }  
}
```

```
 },
"IsEnabled": true
}
```

To exclude only certain Storage Lens groups from being attached to your dashboard configuration, use the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
        "IsEnabled":true
      },
      "StorageLensGroupLevel": {
        "SelectionCriteria": {
          "Exclude": [
            "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slgroup-1",
            "arn:aws:s3:us-east-1:44445556666:storage-lens-group/slgroup-2"
          ]
        },
        "IsEnabled": true
      }
    }
  }
}
```

S3 Storage Lens example tags configuration in JSON

Example tags.json

The tags.json file contains the tags that you want to apply to your S3 Storage Lens configuration. To use this example, replace the *user input placeholders* with your own information.

```
[
```

```
{  
    "Key": "key1",  
    "Value": "value1"  
,  
{  
    "Key": "key2",  
    "Value": "value2"  
}  
]
```

S3 Storage Lens example configuration IAM permissions

Example permissions.json – Specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file with a specific dashboard name specified. Replace *value1*, *us-east-1*, *your-dashboard-name*, and *example-account-id* with your own values.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetStorageLensConfiguration",  
                "s3:DeleteStorageLensConfiguration",  
                "s3:PutStorageLensConfiguration"  
            ],  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/key1": "value1"  
                }  
            },  
            "Resource": "arn:aws:s3:us-east-1:example-account-id:storage-lens/your-dashboard-name"  
        }  
    ]  
}
```

Example permissions.json – No specific dashboard name

This example policy shows an S3 Storage Lens IAM permissions.json file without a specific dashboard name specified. Replace *value1*, *us-east-1*, and *example-account-id* with your own values.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:GetStorageLensConfiguration",  
                "s3:DeleteStorageLensConfiguration",  
                "s3:PutStorageLensConfiguration"  
            ],  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/key1": "value1"  
                }  
            },  
            "Resource": "arn:aws:s3:us-east-1:example-account-id:storage-lens/*"  
        }  
    ]  
}
```

Viewing metrics with Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

By default, all dashboards are configured with free metrics, which include metrics that you can use to understand usage and activity across your S3 storage, optimize your storage costs, and implement data-protection and access-management best practices. Free metrics are aggregated down to the bucket level. With free metrics, data is available for queries for up to 14 days.

Advanced metrics and recommendations include the following additional features that you can use to gain further insight into usage and activity across your storage and best practices for optimizing your storage:

- Contextual recommendations (available only in the dashboard)
- Advanced metrics (including activity metrics aggregated by bucket)
- Prefix aggregation
- Storage Lens group aggregation
- Storage Lens group aggregation
- Amazon CloudWatch publishing

Advanced metrics data is available for queries for 15 months. There are additional charges for using S3 Storage Lens with advanced metrics. For more information, see [Amazon S3 pricing](#). For more information about free and advanced metrics, see [Metrics selection](#).

Topics

- [Viewing S3 Storage Lens metrics on the dashboards](#)
- [Viewing Amazon S3 Storage Lens metrics using a data export](#)
- [Monitor S3 Storage Lens metrics in CloudWatch](#)
- [Amazon S3 Storage Lens metrics use cases](#)

Viewing S3 Storage Lens metrics on the dashboards

In the Amazon S3 console, S3 Storage Lens provides an interactive default dashboard that you can use to visualize insights and trends in your data. You can also use this dashboard to flag outliers and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the account, bucket, AWS Region, prefix, or Storage Lens group level. If you've enabled S3 Storage Lens to work with AWS Organizations, you can also generate insights at the organization level (such as data for all accounts that are part of your AWS Organizations hierarchy). The dashboard always loads for the latest date that has metrics available.

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. Amazon S3 pre-configures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope

of the default dashboard, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing.

You can disable the default dashboard, but you can't delete it. If you disable your default dashboard, it is no longer updated. You also will no longer receive any new daily metrics in S3 Storage Lens or in the **Account snapshot** section on the **Buckets** page. You can still see historic data in the default dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access this data, you can re-enable the default dashboard within the expiration period.

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts. You can also scope your dashboards by organization if you've enabled Storage Lens to work with AWS Organizations. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

You can disable or delete any additional dashboards that you create.

- If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data for free metrics until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access this data, you can re-enable the dashboard within the expiration period.
- If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

- [Understanding your S3 Storage Lens dashboard](#)

Viewing an Amazon S3 Storage Lens dashboard

The following procedure shows how to view an S3 Storage Lens dashboard in the S3 console. For use-case based walkthroughs that show how to use your dashboard to optimize costs, implement

best practices, and improve the performance of applications that access your S3 buckets, see [Amazon S3 Storage Lens metrics use cases](#).

 **Note**

You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required AWS Identity and Access Management (IAM) permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see [Setting Amazon S3 Storage Lens permissions](#) and [Security best practices in IAM](#) in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

Your dashboard opens in S3 Storage Lens. The **Snapshot for date** section shows the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads the latest date that has metrics available.

4. (Optional) To change the date for your S3 Storage Lens dashboard, in the top-right date selector, choose a new date.
5. (Optional) To apply temporary filters to further limit the scope of your dashboard data, do the following:
 - a. Expand the **Filters** section.
 - b. To filter by specific accounts, AWS Regions, storage classes, buckets, prefixes, or Storage Lens groups, choose the options to filter by.

 **Note**

The **Prefixes** filter and the **Storage Lens groups** filter can't be applied at the same time.

- c. To update a filter, choose **Apply**.
- d. To remove a filter, click on the X next to the filter.

6. In any section in your S3 Storage Lens dashboard, to see data for a specific metric, for **Metric**, choose the metric name.
7. In any chart or visualization in your S3 Storage Lens dashboard, you can drill down into deeper levels of aggregation by using the **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes**, or **Storage Lens groups** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

Understanding your S3 Storage Lens dashboard

Your S3 Storage Lens dashboard has a primary **Overview** tab, and up to five additional tabs that represent each aggregation level:

- **Accounts**
- **AWS Regions**
- **Storage classes**
- **Buckets**
- **Prefixes**
- **Storage Lens groups**

On the **Overview** tab, your dashboard data is aggregated into three different sections: **Snapshot for date**, **Trends and distributions**, and **Top N overview**.

For more information about your S3 Storage Lens dashboard, see the following sections.

Snapshot

The **Snapshot for date** section shows summary metrics that S3 Storage Lens has aggregated for the date selected. These summary metrics include the following metrics:

- **Total storage** – The total amount of storage used in bytes.
- **Object count** – The total number of objects in your AWS account.
- **Average object size** – The average object size.
- **Active buckets** – The total number of active buckets in active usage with storage > 0 bytes in your account.
- **Accounts** – The number of accounts whose storage is in scope. This value is **1** unless you are using AWS Organizations and your S3 Storage Lens has trusted access with a valid service-linked role. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

- **Buckets** – The total number of buckets in your account.

Metric data

For each metric that appears in the snapshot, you can see the following data:

- **Metric name** – The name of the metric.
- **Metric category** – The category that the metric is organized into.
- **Total for date** – The total count for the date selected.
- **% change** – The percentage change from the last snapshot date.
- **30-day trend** – A trend-line showing the changes for the metric over a 30-day period.
- **Recommendation** – A contextual recommendation based on the data that's provided in the snapshot. Recommendations are available with advanced metrics and recommendations. For more information, see [Recommendations](#).

Metrics categories

You can optionally update your dashboard **Snapshot for date** section to display metrics for other categories. If you want to see snapshot data for additional metrics, you can choose from the following **Metrics categories**:

- **Cost optimization**
- **Data protection**
- **Activity** (available with advanced metrics)
- **Access management**
- **Performance**
- **Events**

The **Snapshot for date** section displays only a selection of metrics for each category. To see all metrics for a specific category, choose the metric in the **Trends and distributions** or **Top N overview** sections. For more information about metric categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Trends and distributions

The second section of the **Overview** tab is **Trends and distributions**. In the **Trends and distributions** section, you can choose two metrics to compare over a date range that you define. The **Trends and distributions** section shows the relationship between two metrics over time. This section displays charts that you can use to see the **Storage class** and **Region** distribution between the two trends that you are tracking. You can optionally drill down into a data point in one of the charts for deeper analysis.

For a walkthrough that uses the **Trends and distributions** section, see [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#).

Top N overview

The third section of the S3 Storage Lens dashboard is **Top N overview** (sorted in ascending or descending order). This section displays your selected metrics across the top number of accounts, AWS Regions, buckets, prefixes, or Storage Lens groups. If you enabled S3 Storage Lens to work with AWS Organizations, you can also see your selected metrics across your organization.

For a walkthrough that uses the **Top N overview** section, see [Identify your largest S3 buckets](#).

Drill down and analyze by options

To provide a fluid experience for analysis, the S3 Storage Lens dashboard provides an action menu, which appears when you choose any chart value. To use this menu, choose any chart value to see the associated metrics values, and then choose from two options in the box that appears:

- The **Drill down** action applies the selected value as a filter across all tabs of your dashboard. You can then drill down into that value for deeper analysis.
- The **Analyze by** action takes you to the **Dimension** tab that you select and applies that tab value as a filter. These tabs include **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes** (for dashboards that have **Advanced metrics** and **Prefix aggregation** enabled), and **Storage Lens groups** (for dashboards that have **Advanced metrics** and **Storage Lens group aggregation** enabled). With **Analyze by**, you can view the data in the context of the new dimension for deeper analysis.

The **Drill down** and **Analyze by** actions might be disabled if the outcome would yield illogical results or would not have any value. Both the **Drill down** and **Analyze by** actions apply filters on top of any existing filters across all tabs of the dashboard. You can also remove the filters as needed.

Tabs

The dimension-level tabs provide a detailed view of all values within a particular dimension. For example, the **AWS Regions** tab shows metrics for all AWS Regions, and the **Buckets** tab shows metrics for all buckets. Each dimension tab contains an identical layout consisting of four sections:

- A trend chart that displays your top N items within the dimension over the last 30 days for the selected metric. By default, this chart displays the top 10 items, but you can decrease it to at least 3 items or increase it up to 50 items.
- A histogram chart that shows a vertical bar chart for the selected date and metric. If you have a large number of items to display in this chart, you might need to scroll horizontally.
- A bubble analysis chart that plots all items within the dimension. This chart represents the first metric on the x axis and the second metric on the y axis. The third metric is represented by the size of the bubble.
- A metric grid view that contains each item in the dimension listed in rows. The columns represent each available metric, arranged in metrics category tabs for easier navigation.

Viewing Amazon S3 Storage Lens metrics using a data export

Amazon S3 Storage Lens metrics are generated daily in CSV or Apache Parquet-formatted metrics export files and placed in an S3 bucket in your account. From there, you can ingest the metrics export into the analytics tools of your choice, such as Amazon QuickSight and Amazon Athena, where you can analyze storage usage and activity trends.

Topics

- [Using an AWS KMS key to encrypt your metrics exports](#)

- [Understanding the Amazon S3 Storage Lens export schema](#)

Using an AWS KMS key to encrypt your metrics exports

To grant Amazon S3 Storage Lens permission to encrypt your metrics exports by using a customer managed key, you must use a key policy. To update your key policy so that you can use a KMS key to encrypt your S3 Storage Lens metrics exports, follow these steps.

To grant S3 Storage Lens permissions to encrypt data by using your KMS key

1. Sign into the AWS Management Console by using the AWS account that owns the customer managed key.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the **Region selector** in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the key that you want to use to encrypt the metrics exports. AWS KMS keys are Region-specific and must be in the same Region as the metrics export destination S3 bucket.
6. Under **Key policy**, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. Under **Edit key policy**, add the following key policy to the existing key policy. To use this policy, replace the *user input placeholders* with your information.

```
{  
    "Sid": "Allow Amazon S3 Storage Lens use of the KMS key",  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "storage-lens.s3.amazonaws.com"  
    },  
    "Action": [  
        "kms:GenerateDataKey"  
    ],  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:SourceArn": "arn:aws:s3:us-east-1:source-account-id:storage-  
lens/your-dashboard-name",  
            "aws:SourceAccount": "source-account-id"  
        }  
    }  
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following topics in the *AWS Key Management Service Developer Guide*:

- [Getting started](#)
- [Using key policies in AWS KMS](#)

You can also use the AWS KMS PUT key policy API operation ([PutKeyPolicy](#)) to copy the key policy to the customer managed keys that you want to use to encrypt the metrics exports by using the REST API, AWS CLI, and SDKs.

What is an S3 Storage Lens export manifest?

Given the large amount of data aggregated, an S3 Storage Lens daily metrics export can be split into multiple files. The manifest file `manifest.json` describes where the metrics export files for that day are located. Whenever a new export is delivered, it is accompanied by a new manifest. Each manifest contained in the `manifest.json` file provides metadata and other basic information about the export.

The manifest information includes the following properties:

- `sourceAccountId` – The account ID of the configuration owner.
- `configId` – A unique identifier for the dashboard.
- `destinationBucket` – The destination bucket Amazon Resource Name (ARN) that the metrics export is placed in.
- `reportVersion` – The version of the export.
- `reportDate` – The date of the report.
- `reportFormat` – The format of the report.
- `reportSchema` – The schema of the report.
- `reportFiles` – The actual list of the export report files that are in the destination bucket.

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted export.

```
{  
  "sourceAccountId": "123456789012",  
  "configId": "my-dashboard-configuration-id",  
  "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
  "reportVersion": "V_1",  
  "reportDate": "2020-11-03",  
  "files": [  
    {  
      "file": "file1.csv",  
      "format": "CSV",  
      "schema": "S3Object",  
      "version": "V_1",  
      "date": "2020-11-03T12:00:00Z"  
    },  
    {  
      "file": "file2.csv",  
      "format": "CSV",  
      "schema": "S3Object",  
      "version": "V_1",  
      "date": "2020-11-03T12:00:00Z"  
    }  
  ]  
}
```

```
"reportFormat": "CSV",  
  
"reportSchema": "version_number,configuration_id,report_date,aws_account_number,aws_region,stor  
"reportFiles": [  
    {  
        "key": "DestinationPrefix/StorageLens/123456789012/my-dashboard-  
configuration-id/V_1/reports/dt=2020-11-03/a38f6bc4-2e3d-4355-ac8a-e2fdcf3de158.csv",  
        "size": 1603959,  
        "md5Checksum": "2177e775870def72b8d84febe1ad3574"  
    }  
]  
}
```

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted export.

```
{  
    "sourceAccountId": "123456789012",  
    "configId": "my-dashboard-configuration-id",  
    "destinationBucket": "arn:aws:s3:::amzn-s3-demo-destination-bucket",  
    "reportVersion": "V_1",  
    "reportDate": "2020-11-03",  
    "reportFormat": "Parquet",  
    "reportSchema": "message s3.storage.lens { required string version_number;  
required string configuration_id; required string report_date; required string

}
```

You can configure your metrics export to be generated as part of your dashboard configuration in the Amazon S3 console or by using the Amazon S3 REST API, AWS CLI, and SDKs.

Understanding the Amazon S3 Storage Lens export schema

The following table contains the schema of your S3 Storage Lens metrics export.

Attribute name	Data type	Column name	Description
VersionNumber	String	version_number	The version of the S3 Storage Lens metrics being used.
ConfigurationId	String	configuration_id	The configuration_id of your S3 Storage Lens configuration.
ReportDate	String	report_date	The date that the metrics were tracked.
AwsAccountNumber	String	aws_account_number	Your AWS account number.
AwsRegion	String	aws_region	The AWS Region for which the metrics are being tracked.
StorageClass	String	storage_class	The storage class of the bucket in question.
RecordType	ENUM	record_type	The type of artifact that is being reported (ACCOUNT, BUCKET, or PREFIX).
RecordValue	String	record_value	The value of the RecordType artifact.

 **Note**

The record_va

Attribute name	Data type	Column name	Description
			Value is URL-encoded.
BucketName	String	bucket_name	The name of the bucket that is being reported.
MetricName	String	metric_name	The name of the metric that is being reported.
MetricValue	Long	metric_value	The value of the metric that is being reported.

Example of an S3 Storage Lens metrics export

The following is an example of an S3 Storage Lens metrics export based on this schema.

Note

You can identify metrics for Storage Lens groups by looking for the STORAGE_LENS_GROUP_BUCKET or STORAGE_LENS_GROUP_ACCOUNT values in the record_type column. The record_value column will display the Amazon Resource Name (ARN) for the Storage Lens group, for example, arn:aws:s3:us-east-1:123456789012:storage-lens-group/slgl-1.

version_r	configuration_id	report_date	aws_account_number	aws_region	storage_class	record_type	record_value	bucket_name	metric_name	metric_value

The following is an example of an S3 Storage Lens metrics export with Storage Lens groups data.

Monitor S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs. Dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations can use the CloudWatch publishing option. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

 **Note**

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

After you enable the CloudWatch publishing option, you can use the following CloudWatch features to monitor and analyze your S3 Storage Lens data:

- [Dashboards](#) – Use CloudWatch dashboards to create customized S3 Storage Lens dashboards. Share your CloudWatch dashboard with people who don't have direct access to your AWS account, across teams, with stakeholders, and with people external to your organizations.
- [Alarms and triggered actions](#) – Configure alarms that watch metrics and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.
- [Anomaly detection](#) – Enable anomaly detection to continuously analyze metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on

the expected value of a metric. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

- [Metric math](#) – You can also use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric to get the average object size by dividing `StorageBytes` by `ObjectCount`.

For more information about the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Topics

- [S3 Storage Lens metrics and dimensions](#)
- [Enabling CloudWatch publishing for S3 Storage Lens](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

S3 Storage Lens metrics and dimensions

To send S3 Storage Lens metrics to CloudWatch, you must enable the CloudWatch publishing option within S3 Storage Lens advanced metrics and recommendations. After advanced metrics are enabled, you can use [CloudWatch dashboards](#) to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. You can use dimensions to filter your S3 Storage Lens metrics in CloudWatch by organization, account, bucket, storage class, Region, and metrics configuration ID.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for

S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

For more information about S3 Storage Lens metrics and dimensions in CloudWatch, see the following topics.

Topics

- [Metrics](#)
- [Dimensions](#)

Metrics

S3 Storage Lens metrics are available as metrics within CloudWatch. S3 Storage Lens metrics are published to the AWS/S3/Storage-Lens namespace. This namespace is only for S3 Storage Lens metrics. Amazon S3 bucket, request, and replication metrics are published to the AWS/S3 namespace.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

In S3 Storage Lens, metrics are aggregated and stored only in the designated home Region. S3 Storage Lens metrics are also published to CloudWatch in the home Region that you specify in the S3 Storage Lens configuration.

For a complete list of S3 Storage Lens metrics, including a list of those metrics available in CloudWatch, see [Amazon S3 Storage Lens metrics glossary](#).

Note

The valid statistic for S3 Storage Lens metrics in CloudWatch is Average. For more information about statistics in CloudWatch, see [CloudWatch statistics definitions in the Amazon CloudWatch User Guide](#).

Granularity of S3 Storage Lens metrics in CloudWatch

S3 Storage Lens offers metrics at organization, account, bucket, and prefix granularity. S3 Storage Lens publishes organization, account, and bucket-level S3 Storage Lens metrics to CloudWatch. Prefix-level S3 Storage Lens metrics are not available in CloudWatch.

For more information about the granularity of S3 Storage Lens metrics available in CloudWatch, see the following list:

- **Organization** – Metrics aggregated across the member accounts in your organization. S3 Storage Lens publishes metrics for member accounts to CloudWatch in the management account.
 - **Organization and account** – Metrics for the member accounts in your organization.
 - **Organization and bucket** – Metrics for Amazon S3 buckets in the member accounts of your organization.
- **Account** (Non-organization level) – Metrics aggregated across the buckets in your account.
- **Bucket** (Non-organization level) – Metrics for a specific bucket. In CloudWatch, S3 Storage Lens publishes these metrics to the AWS account that created the S3 Storage Lens configuration. S3 Storage Lens publishes these metrics only for non-organization configurations.

Dimensions

When S3 Storage Lens sends data to CloudWatch, dimensions are attached to each metric.

Dimensions are categories that describe the characteristics of metrics. You can use dimensions to filter the results that CloudWatch returns.

For example, all S3 Storage Lens metrics in CloudWatch have the `configuration_id` dimension. You can use this dimension to differentiate between metrics associated with a specific S3 Storage Lens configuration. The `organization_id` identifies organization-level metrics. For more information about dimensions in CloudWatch, see [Dimensions](#) in the *CloudWatch User Guide*.

Different dimensions are available for S3 Storage Lens metrics depending on the granularity of the metrics. For example, you can use the `organization_id` dimension to filter organization-level metrics by the AWS Organizations ID. However, you can't use this dimension for bucket and account-level metrics. For more information, see [Filtering metrics using dimensions](#).

To see which dimensions are available for your S3 Storage Lens configuration, see the following table.

Dimension	Description	Bucket	Organization	Account	Bucket and account	Bucket count
configuration_id	The dashboard name for the S3 Storage Lens configuration reported in the metrics	•	•	•	•	•
metrics_version	The version of the S3 Storage Lens metrics. The metrics version has a fixed value of 1.0.	•	•	•	•	•
organization_id	The AWS Organizations ID for the metrics	•	•	•	•	•
aws_account_number	The AWS account that's associated with the metrics	•	•	•	•	•
aws_region	The AWS Region for the metrics	•	•	•	•	•
bucket_name	The name of the S3 bucket that's reported in the metrics	•	•	•	•	•
storage_class	The storage class for the bucket that's reported in the metrics	•	•	•	•	•
record_type	The granularity of the metrics: ORGANIZATION, ACCOUNT, BUCKET	•	•	•	•	ORGANIZATION BUCKET ACCOUNT

Enabling CloudWatch publishing for S3 Storage Lens

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications,

including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

You can enable CloudWatch support for new or existing dashboard configurations by using the S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply.

To enable the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

Using the S3 console

When you update an S3 Storage Lens dashboard, you can't change the dashboard name or home Region. You also can't change the scope of the default dashboard, which is scoped to your entire account's storage.

To update an S3 Storage Lens dashboard to enable CloudWatch publishing

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **S3 Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.
4. Under **Metrics selection**, choose **Advanced metrics and recommendations**.

Advanced metrics and recommendations are available for an additional charge. Advanced metrics and recommendations include a 15-month period for data queries, usage metrics aggregated at the prefix level, activity metrics aggregated by bucket, the CloudWatch publishing option, and contextual recommendations that help you optimize storage costs and apply data-protection best practices. For more information, see [Amazon S3 pricing](#).

5. Under **Select Advanced metrics and recommendations features**, select **CloudWatch publishing**.

⚠ Important

If your configuration enables prefix aggregation for usage metrics, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

6. Choose **Save changes**.

To create a new S3 Storage Lens dashboard that enables CloudWatch support

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose **Create dashboard**.
4. Under **General**, define the following configuration options:
 - a. For **Dashboard name**, enter your dashboard name.

Dashboard names must be fewer than 65 characters and must not contain special characters or spaces. You can't change the dashboard name after you create your dashboard.
 - b. Choose the **Home Region** for your dashboard.

Metrics for all Regions included in this dashboard scope are stored centrally in the designated home Region. In CloudWatch, S3 Storage Lens metrics are also available in the home Region. You can't change the home Region after you create your dashboard.

5. (Optional) To add tags, choose **Add tag** and enter the tag **Key** and **Value**.

 **Note**

You can add up to 50 tags to your dashboard configuration.

6. Define the scope for your configuration:

- a. If you're creating an organization-level configuration, choose the accounts to include in the configuration: **Include all accounts in your configuration** or **Limit the scope to your signed-in account**.

 **Note**

When you create an organization-level configuration that includes all accounts, you can include or exclude only Regions, not buckets.

- b. Choose the Regions and buckets that you want S3 Storage Lens to include in the dashboard configuration by doing the following:
 - To include all Regions, choose **Include Regions and buckets**.
 - To include specific Regions, clear **Include all Regions**. Under **Choose Regions to include**, choose the Regions that you want S3 Storage Lens to include in the dashboard.
 - To include specific buckets, clear **Include all buckets**. Under **Choose buckets to include**, choose the buckets that you want S3 Storage Lens to include in the dashboard.

 **Note**

You can choose up to 50 buckets.

7. For **Metrics selection**, choose **Advanced metrics and recommendations**.

For more information about advanced metrics and recommendations pricing, see [Amazon S3 pricing](#).

8. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

- **Advanced metrics**
- **CloudWatch publishing**

 **Important**

If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

- **Prefix aggregation**

 **Note**

For more information about advanced metrics and recommendations features, see [Metrics selection](#).

9. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

- **Activity metrics**
- **Detailed status code metrics**
- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information about metrics categories, see [Metrics categories](#). For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

10. (Optional) Configure your metrics export.

For more information about how to configure a metrics export, see step [Using the S3 console](#).

11. Choose **Create dashboard**.

Using the AWS CLI

The following AWS CLI example enables the CloudWatch publishing option by using a S3 Storage Lens organization-level advanced metrics and recommendations configuration. To use this example, replace the *user input placeholders* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./config.json

config.json
{
    "Id": "SampleS3StorageLensConfiguration", //Use this property to identify your S3 Storage Lens configuration.
    "AwsOrg": { //Use this property when enabling S3 Storage Lens for AWS Organizations.

Using the REST API

To enable the CloudWatch publishing option by using the Amazon S3 REST API, you can use [PutStorageLensConfiguration](#).

Next steps

After you enable the CloudWatch publishing option, you can access your S3 Storage Lens metrics in CloudWatch. You also can leverage CloudWatch features to monitor and analyze your S3 Storage Lens data in CloudWatch. For more information, see the following topics:

- [S3 Storage Lens metrics and dimensions](#)
- [Working with S3 Storage Lens metrics in CloudWatch](#)

Working with S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in [CloudWatch dashboards](#). You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the [Amazon CloudWatch User Guide](#).

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see [Amazon S3 pricing](#). No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see [Amazon CloudWatch pricing](#).

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day.

When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

For more information about working with S3 Storage Lens metrics in CloudWatch, see the following topics.

Topics

- [Working with CloudWatch dashboards](#)
- [Setting alarms, triggering actions, and using anomaly detection](#)
- [Filtering metrics using dimensions](#)
- [Calculating new metrics with metric math](#)
- [Using search expressions in graphs](#)

Working with CloudWatch dashboards

You can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view.

CloudWatch has broad permissions control that doesn't support limiting access to a specific set of metrics or dimensions. Users in your account or organization who have access to CloudWatch will have access to metrics for all S3 Storage Lens configurations where the CloudWatch support option is enabled. You can't manage permissions for specific dashboards as you can in S3 Storage Lens. For more information about CloudWatch permissions, see [Managing access permissions to your CloudWatch resources](#) in the *Amazon CloudWatch User Guide*.

For more information about using CloudWatch dashboards and configuring permissions, see [Using Amazon CloudWatch dashboards](#) and [Sharing CloudWatch dashboards](#) in the *Amazon CloudWatch User Guide*.

Setting alarms, triggering actions, and using anomaly detection

You can configure CloudWatch alarms that watch S3 Storage Lens metrics in CloudWatch and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

You can also enable anomaly detection to continuously analyze your S3 Storage Lens metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on a metric's expected value. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

For more information and examples, see [Using Amazon CloudWatch alarms](#) and [Creating an alarm from a metric on a graph](#) in the *Amazon CloudWatch User Guide*.

Filtering metrics using dimensions

You can use dimensions to filter S3 Storage Lens metrics in the CloudWatch console. For example, you can filter by `configuration_id`, `aws_account_number`, `aws_region`, `bucket_name`, and more.

S3 Storage Lens supports multiple dashboard configurations per account. This means that different configurations can include the same bucket. When these metrics are published to CloudWatch, the bucket will have duplicate metrics within CloudWatch. To view metrics only for a specific S3 Storage Lens configuration in CloudWatch, you can use the `configuration_id` dimension. When you filter by `configuration_id`, you see only the metrics that are associated with the configuration that you identify.

For more information about filtering by configuration ID, see [Searching for available metrics](#) in the *Amazon CloudWatch User Guide*.

Calculating new metrics with metric math

You can use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric for unencrypted objects by subtracting Encrypted Objects from Object Count. You can also create a

metric to get the average object size by dividing `StorageBytes` by `ObjectCount` or the number bytes accessed on one day by dividing `BytesDownloaded` by `StorageBytes`.

For more information, see [Using metric math](#) in the *Amazon CloudWatch User Guide*.

Using search expressions in graphs

With S3 Storage Lens metrics, you can create a search expression. For example, you can create a search expression for all metrics that are named `IncompleteMultipartUploadStorageBytes` and add `SUM` to the expression. With this search expression, you can see your total incomplete multipart upload bytes across all dimensions of your storage in a single metric.

This example shows the syntax that you would use to create a search expression for all metrics named `IncompleteMultipartUploadStorageBytes`.

```
SUM(SEARCH( '{AWS/S3/Storage-  
Lens,aws_account_number,aws_region,configuration_id,metrics_version,record_type,storage_class}  
MetricName="IncompleteMultipartUploadStorageBytes"', 'Average',86400))
```

For more information about this syntax, see [CloudWatch search expression syntax](#) in the *Amazon CloudWatch User Guide*. To create a CloudWatch graph with a search expression, see [Creating a CloudWatch graph with a search expression](#) in the *Amazon CloudWatch User Guide*.

Amazon S3 Storage Lens metrics use cases

You can use your Amazon S3 Storage Lens dashboard to visualize insights and trends, flag outliers, and receive recommendations. S3 Storage Lens metrics are organized into categories that align with key use cases. You can use these metrics to do the following:

- Identify cost-optimization opportunities
- Apply data-protection best practices
- Apply access-management best practices
- Improve the performance of application workloads

For example, with cost-optimization metrics, you can identify opportunities to reduce your Amazon S3 storage costs. You can identify buckets with multipart uploads that are more than 7-days old or buckets that are accumulating noncurrent versions.

Similarly, you can use data-protection metrics to identify buckets that aren't following data-protection best practices within your organization. For example, you can identify buckets that

don't use AWS Key Management Service keys (SSE-KMS) for default encryption or don't have S3 Versioning enabled.

With S3 Storage Lens access-management metrics, you can identify bucket settings for S3 Object Ownership so that you can migrate access control list (ACL) permissions to bucket policies and disable ACLs.

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests that you can use to troubleshoot access or performance issues.

With advanced metrics, you can also access additional cost-optimization and data-protection metrics that you can use to identify opportunities to further reduce your overall S3 storage costs and better align with best practices for protecting your data. For example, advanced cost-optimization metrics include lifecycle rule counts that you can use to identify buckets that don't have lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. Advanced data-protection metrics include replication rule counts.

For more information about metrics categories, see [Metrics categories](#). For a complete list of S3 Storage Lens metrics, see [Amazon S3 Storage Lens metrics glossary](#).

Topics

- [Using S3 Storage Lens to protect your data](#)
- [Using S3 Storage Lens to audit Object Ownership settings](#)
- [Using S3 Storage Lens metrics to improve performance](#)

Using Amazon S3 Storage Lens to optimize your storage costs

You can use S3 Storage Lens cost-optimization metrics to reduce the overall cost of your S3 storage. Cost-optimization metrics can help you confirm that you've configured Amazon S3 cost effectively and according to best practices. For example, you can identify the following cost-optimization opportunities:

- Buckets with incomplete multipart uploads older than 7 days
- Buckets that are accumulating numerous noncurrent versions
- Buckets that don't have lifecycle rules to abort incomplete multipart uploads
- Buckets that don't have lifecycle rules to expire noncurrent versions objects

- Buckets that don't have lifecycle rules to transition objects to a different storage class

You can then use this data to add additional lifecycle rules to your buckets.

The following examples show how you can use cost- optimization metrics in your S3 Storage Lens dashboard to optimize your storage costs.

Topics

- [Identify your largest S3 buckets](#)
- [Uncover cold Amazon S3 buckets](#)
- [Locate incomplete multipart uploads](#)
- [Reduce the number of noncurrent versions retained](#)
- [Identify buckets that don't have lifecycle rules and review lifecycle rule counts](#)

Identify your largest S3 buckets

You pay for storing objects in S3 buckets. The rate that you're charged depends on your objects' sizes, how long you store the objects, and their storage classes. With S3 Storage Lens, you get a centralized view of all the buckets in your account. To see all the buckets in all of your organization's accounts, you can configure an AWS Organizations-level S3 Storage Lens dashboard. From this dashboard view, you can identify your largest buckets.

Step 1: Identify your largest buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

When the dashboard opens, you can see the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads to the latest date that has metrics available.

4. To see a ranking of your largest buckets by the **Total storage** metric for a selected date range, scroll down to the **Top N overview for date** section.

You can toggle the sort order to show the smallest buckets. You can also adjust the **Metric** selection to rank your buckets by any of the available metrics. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line

to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For more detailed insights about your buckets, scroll up to the top of the page, and then choose the **Bucket** tab.

On the **Bucket** tab, you can see details such as the recent growth rate, the average object size, the largest prefixes, and the number of objects.

Step 2: Navigate to your buckets and investigate

After you've identified your largest S3 buckets, you can navigate to each bucket within the S3 console to view the objects in the bucket, understand its associated workload, and identify its internal owners. You can contact the bucket owners to find out whether the growth is expected or whether the growth needs further monitoring and control.

Uncover cold Amazon S3 buckets

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use [activity metrics](#) to understand how cold your S3 buckets are. A "cold" bucket is one whose storage is no longer accessed (or very rarely accessed). This lack of activity typically indicates that the bucket's objects aren't frequently accessed.

Activity metrics, such as **GET Requests** and **Download Bytes**, indicate how often your buckets are accessed each day. To understand the consistency of the access pattern and to spot buckets that are no longer being accessed at all, you can trend this data over several months. The **Retrieval rate** metric, which is computed as **Download bytes / Total storage**, indicates the proportion of storage in a bucket that is accessed daily.

 **Note**

Download bytes are duplicated in cases where the same object is downloaded multiple times during the day.

Prerequisite

To see activity metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Activity metrics**. For more information, see [Using the S3 console](#).

Step 1: Identify active buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. Choose the **Bucket** tab, and then scroll down to the **Bubble analysis by buckets for date** section.

In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

5. To find buckets that have gone cold, for **X-axis**, **Y-axis**, and **Size**, choose the **Total storage**, **% retrieval rate**, and **Average object size** metrics.
6. In the **Bubble analysis by buckets for date** section, locate any buckets with retrieval rates of zero (or near zero) and a larger relative storage size, and choose the bubble that represents the bucket.

A box will appear with choices for more granular insights. Do one of the following:

- a. To update the **Bucket** tab to display metrics only for the selected bucket, choose **Drill down**, and then choose **Apply**.
- b. To aggregate your bucket-level data to by account, AWS Region, storage class, or bucket, choose **Analyze by** and then make a choice for **Dimension**. For example, to aggregate by storage class, choose **Storage class** for **Dimension**.

To find buckets that have gone cold, do a bubble analysis using the **Total storage**, **% retrieval rate**, and **Average object size** metrics. Look for any buckets with retrieval rates of zero (or near zero) and a larger relative storage size.

The **Bucket** tab of your dashboard updates to display data for your selected aggregation or filter. If you aggregated by storage class or another dimension, that new tab opens in your dashboard (for example, the **Storage class** tab).

Step 2: Investigate cold buckets

From here, you can identify the owners of cold buckets in your account or organization and find out if that storage is still needed. You can then optimize costs by configuring [lifecycle expiration configurations](#) for these buckets or archiving the data in one of the [Amazon S3 Glacier storage classes](#).

To avoid the problem of cold buckets going forward, you can [automatically transition your data by using S3 Lifecycle configurations](#) for your buckets, or you can enable [auto-archiving with S3 Intelligent-Tiering](#).

You can also use step 1 to identify hot buckets. Then, you can ensure that these buckets use the correct [S3 storage class](#) to ensure that they serve their requests most effectively in terms of performance and cost.

Locate incomplete multipart uploads

You can use multipart uploads to upload very large objects (up to 5 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state). These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).

With S3 Storage Lens, you can identify the number of incomplete multipart upload bytes in your account or across your entire organization, including incomplete multipart uploads that are more than 7 days old. For a complete list of incomplete multipart upload metrics, see [Amazon S3 Storage Lens metrics glossary](#).

As a best practice, we recommend configuring lifecycle rules to expire incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point.

Step 1: Review overall trends for incomplete multipart uploads

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metrics categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include **Incomplete multipart upload bytes greater than 7 days old**.

In any chart in your S3 Storage Lens dashboard, you can see metrics for incomplete multipart uploads. You can use these metrics to further assess the impact of incomplete multipart upload bytes on your storage, including their contribution to overall growth trends. You can also drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Bucket**, or **Storage class** tabs for a deeper analysis of your data. For an example, see [Uncover cold Amazon S3 buckets](#).

Step 2: Identify buckets that have the most incomplete multipart upload bytes but don't have lifecycle rules to abort incomplete multipart uploads

Prerequisite

To see the **Abort incomplete multipart upload lifecycle rule count** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets that are accumulating incomplete multipart uploads greater than 7 days old, go to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. You can increase or decrease the number of buckets in the **Top N** field. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. (This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.)

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Incomplete multipart upload bytes greater than 7 days old** in the **Cost optimization** category.

Under **Top number buckets**, you can see the buckets with the most incomplete multipart upload storage bytes that are greater than 7 days old.

6. To view more detailed bucket-level metrics for incomplete multipart uploads, scroll to the top of the page, and then choose the **Bucket** tab.
7. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

8. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
9. Clear the toggles for all cost-optimization metrics until only **Incomplete multipart upload bytes greater than 7 days old** and **Abort incomplete multipart upload lifecycle rule count** remain selected.
10. (Optional) Under **Page size**, choose the number of buckets to display in the list.
11. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for incomplete multipart uploads and lifecycle rule counts. You can use this data to identify buckets that have the most incomplete multipart upload bytes that are greater than 7 days old and are missing lifecycle rules to abort incomplete multipart uploads. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to delete abandoned incomplete multipart uploads.

Step 3: Add a lifecycle rule to delete incomplete multipart uploads after 7 days

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle configuration to expire incomplete multipart upload bytes from a bucket after a specified number of days. For more information, see [Configuring a bucket lifecycle configuration to delete incomplete multipart uploads](#).

Reduce the number of noncurrent versions retained

When enabled, S3 Versioning retains multiple distinct copies of the same object that you can use to quickly recover data if an object is accidentally deleted or overwritten. If you've enabled S3 Versioning without configuring lifecycle rules to transition or expire noncurrent versions, a large number of previous noncurrent versions can accumulate, which can have storage-cost implications. For more information, see [Retaining multiple versions of objects with S3 Versioning](#).

Step 1: Identify buckets with the most noncurrent object versions

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metric categories**, choose **Cost optimization**.

The **Snapshot for date** section updates to display **Cost optimization** metrics, which include the metric for **% noncurrent version bytes**. The **% noncurrent version bytes** metric represents the proportion of your total storage bytes that is attributed to noncurrent versions, within the dashboard scope and for the selected date.

 **Note**

If your **% noncurrent version bytes** is greater than 10 percent of your storage at the account level, you might be storing too many object versions.

5. To identify specific buckets that are accumulating a large number of noncurrent versions:
 - a. Scroll down to the **Top N overview for date** section. For **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **% noncurrent version bytes**.

Under **Top number buckets**, you can see the buckets (for the number that you specified) with the highest **% noncurrent version bytes**. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

- c. To view more detailed bucket-level metrics for noncurrent object versions, scroll to the top of the page, and then choose the **Bucket** tab.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

- d. In the **Buckets** section, for **Metric categories**, select **Cost optimization**. Then, clear **Summary**.

You can now see the **% noncurrent version bytes** metric, along with other metrics related to noncurrent versions.

Step 2: Identify buckets that are missing transition and expiration lifecycle rules for managing noncurrent versions

Prerequisite

To see the **Noncurrent version transition lifecycle rule count** and **Noncurrent version expiration lifecycle rule count** metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metric categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **% noncurrent version bytes**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display metrics for noncurrent version bytes and noncurrent version lifecycle rule counts. You can use this data to identify buckets that have a high percentage of noncurrent version bytes but are missing transition and expiration lifecycle rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules to transition or expire noncurrent object versions

After you've determined which buckets require further investigation, you can navigate to the buckets within the S3 console and add a lifecycle rule to expire noncurrent versions after a specified number of days. Alternatively, to reduce costs while still retaining noncurrent versions, you can configure a lifecycle rule to transition noncurrent versions to one of the Amazon S3 Glacier storage classes. For more information, see [Specifying a lifecycle rule for a versioning-enabled bucket](#).

Identify buckets that don't have lifecycle rules and review lifecycle rule counts

S3 Storage Lens provides S3 Lifecycle rule count metrics that you can use to identify buckets that are missing lifecycle rules. To find buckets that don't have lifecycle rules, you can use the **Total buckets without lifecycle rules** metric. A bucket with no S3 Lifecycle configuration might have storage that you no longer need or can migrate to a lower-cost storage class. You can also use lifecycle rule count metrics to identify buckets that are missing specific types of lifecycle rules, such as expiration or transition rules.

Prerequisite

To see lifecycle rule count metrics and the **Total buckets without lifecycle rules** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see [Using the S3 console](#).

Step 1: Identify buckets without lifecycle rules

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets without lifecycle rules, scroll down to the **Top N overview for date** section.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

 **Note**

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

5. For **Metric**, choose **Total buckets without lifecycle rules** from the **Cost optimization** category.
6. Review the following data for **Total buckets without lifecycle rules**:
 - **Top number accounts** - See which accounts that have the most buckets without lifecycle rules.
 - **Top number Regions** - View a breakdown of buckets without lifecycle rules by Region.
 - **Top number buckets** - See which buckets don't have lifecycle rules.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see [Uncover cold Amazon S3 buckets](#).

After you identify which buckets don't have lifecycle rules, you can also review specific lifecycle rule counts for your buckets.

Step 2: Review lifecycle rule counts for your buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your S3 Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
 - **Transition lifecycle rule count**
 - **Expiration lifecycle rule count**
 - **Noncurrent version transition lifecycle rule count**
 - **Noncurrent version expiration lifecycle rule count**
 - **Abort incomplete multipart upload lifecycle rule count**
 - **Total lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display lifecycle rule count metrics for your buckets. You can use this data to identify buckets without lifecycle rules or buckets that are missing specific kinds of lifecycle rules, for example, expiration or transition rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules

After you've identified buckets with no lifecycle rules, you can add lifecycle rules. For more information, see [Setting an S3 Lifecycle configuration on a bucket](#) and [Examples of S3 Lifecycle configurations](#).

Using S3 Storage Lens to protect your data

You can use Amazon S3 Storage Lens data-protection metrics to identify buckets where data-protection best practices haven't been applied. You can use these metrics to take action and apply standard settings that align with best practices for protecting your data across the buckets in your account or organization. For example, you can use data-protection metrics to identify buckets that don't use AWS Key Management Service (AWS KMS) keys (SSE-KMS) for default encryption or requests that use AWS Signature Version 2 (SigV2).

The following use cases provide strategies for using your S3 Storage Lens dashboard to identify outliers and apply data-protection best practices across your S3 buckets.

Topics

- [Identify buckets that don't use server-side encryption with AWS KMS for default encryption \(SSE-KMS\)](#)
- [Identify buckets that have S3 Versioning enabled](#)
- [Identify requests that use AWS Signature Version 2 \(SigV2\)](#)
- [Count the total number of replication rules for each bucket](#)
- [Identify percentage of Object Lock bytes](#)

Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

With Amazon S3 default encryption, you can set the default encryption behavior for an S3 bucket. For more information, see [the section called "Setting default bucket encryption"](#).

You can use the **SSE-KMS enabled bucket count** and **% SSE-KMS enabled buckets** metrics to identify buckets that use server-side encryption with AWS KMS keys (SSE-KMS) for default encryption. S3 Storage Lens also provides metrics for unencrypted bytes, unencrypted objects, encrypted bytes, and encrypted objects. For a complete list of metrics, see [Amazon S3 Storage Lens metrics glossary](#).

You can analyze SSE-KMS encryption metrics in the context of general encryption metrics to identify buckets that don't use SSE-KMS. If you want to use SSE-KMS for all the buckets in your account or organization, you can then update the default encryption settings for these buckets to use SSE-KMS. In addition to SSE-KMS, you can use server-side encryption with Amazon S3 managed keys (SSE-S3) or customer-provided keys (SSE-C). For more information, see [Protecting data with encryption](#).

Step 1: Identify which buckets are using SSE-KMS for default encryption

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **% SSE-KMS enabled bucket count** for the primary metric and **% encrypted bytes** for the secondary metric.

The **Trend for date** chart updates to display trends for SSE-KMS and encrypted bytes.

5. To view more granular, bucket-level insights for SSE-KMS:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose the **Buckets** dimension. Then choose **Apply**.
6. In the **Distribution by buckets for date** chart, choose the **SSE-KMS enabled bucket count** metric.
7. You can now see which buckets have SSE-KMS enabled and which do not.

Step 2: Update bucket default encryption settings

Now that you've determined which buckets use SSE-KMS in the context of your **% encrypted bytes**, you can identify buckets that don't use SSE-KMS. You can then optionally navigate to these buckets within the S3 console and update their default encryption settings to use SSE-KMS or SSE-S3. For more information, see [Configuring default encryption](#).

Identify buckets that have S3 Versioning enabled

When enabled, the S3 Versioning feature retains multiple versions of the same object that can be used to quickly recover data if an object is accidentally deleted or overwritten. You can use the **Versioning-enabled bucket count** metric to see which buckets use S3 Versioning. Then, you can take action in the S3 console to enable S3 Versioning for other buckets.

Step 1: Identify buckets that have S3 Versioning enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **Versioning-enabled bucket count** for the primary metric and **Buckets** for the secondary metric.

The **Trend for date** chart updates to display trends for S3 Versioning enabled buckets. Right below the trends line, you can see the **Storage class distribution** and **Region distribution** subsections.

5. To view more granular insights for any of the buckets that you see in the **Trend for date** chart so that you can perform a deeper analysis, do the following:
 - a. Choose a point on the chart. A box will appear with choices for more granular insights.
 - b. Choose a dimension to apply to your data for deeper analysis: **Account**, **AWS Region**, **Storage class**, or **Bucket**. Then choose **Apply**.
6. In the **Bubble analysis by buckets for date** section, choose the **Versioning-enabled bucket count**, **Buckets**, and **Active buckets** metrics.

The **Bubble analysis by buckets for date** section updates to display data for the metrics that you selected. You can use this data to see which buckets have S3 Versioning enabled in the context of your total bucket count. In the **Bubble analysis by buckets for date** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

Step 2: Enable S3 Versioning

After you've identified buckets that have S3 Versioning enabled, you can identify buckets that have never had S3 Versioning enabled or are versioning suspended. Then, you can optionally enable versioning for these buckets in the S3 console. For more information, see [Enabling versioning on buckets](#).

Identify requests that use AWS Signature Version 2 (SigV2)

You can use the **All unsupported signature requests** metric to identify requests that use AWS Signature Version 2 (SigV2). This data can help you identify specific applications that are using SigV2. You can then migrate these applications to AWS Signature Version 4 (SigV4).

SigV4 is the recommended signing method for all new S3 applications. SigV4 provides improved security and is supported in all AWS Regions. For more information, see [Amazon S3 update - SigV2 deprecation period extended & modified](#).

Prerequisite

To see **All unsupported signature requests** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Using the S3 console](#).

Step 1: Examine SigV2 signing trends by AWS account, Region, and bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To identify specific buckets, accounts, and Regions with requests that use SigV2:
 - a. Under **Top N overview for date**, in **Top N**, enter the number of buckets that you would like to see data for.
 - b. For **Metric**, choose **All unsupported signature requests** from the **Data protection** category.

The **Top N overview for date** updates to display data for SigV2 requests by account, AWS Region, and bucket. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

Step 2: Identify buckets that are accessed by applications through SigV2 requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.

The **Buckets** list updates to display all the available **Data protection** metrics for the buckets shown.

6. To filter the **Buckets** list to display only specific data-protection metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the following metrics remain selected:
 - **All unsupported signature requests**
 - **% all unsupported signature requests**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for SigV2 requests. You can use this data to identify specific buckets that have SigV2 requests. Then, you can use this information to migrate your applications to SigV4. For more information, see [Authenticating Requests \(AWS Signature Version 4\)](#) in the *Amazon Simple Storage Service API Reference*.

Count the total number of replication rules for each bucket

S3 Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. For more information, see [Replicating objects within and across Regions](#).

You can use S3 Storage Lens replication rule count metrics to get detailed per-bucket information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions.

Prerequisite

To see replication rule count metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see [Using the S3 console](#).

Step 1: Count the total number of replication rules for each bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
6. To filter the **Buckets** list to display only replication rule count metrics, choose the preferences icon ).
7. Clear the toggles for all data-protection metrics until only the replication rule count metrics remain selected:
 - **Same-Region Replication rule count**
 - **Cross-Region Replication rule count**
 - **Same-account replication rule count**
 - **Cross-account replication rule count**
 - **Total replication rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

Step 2: Add replication rules

After you have a per-bucket replication rule count, you can optionally create additional replication rules. For more information, see [Examples for configuring live replication](#).

Identify percentage of Object Lock bytes

With S3 Object Lock, you can store objects by using a *write-once-read-many (WORM)* model. You can use Object Lock to help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can enable Object Lock only when you create a bucket and also enable S3 Versioning. However, you can edit the retention period for individual object versions or apply legal holds for buckets that have Object Lock enabled. For more information, see [Locking objects with Object Lock](#).

You can use Object Lock metrics in S3 Storage Lens to see the **% Object Lock bytes** metric for your account or organization. You can use this information to identify buckets in your account or organization that aren't following your data-protection best practices.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot** section, under **Metrics categories**, choose **Data protection**.

The **Snapshot** section updates to display data-protection metrics, including the **% Object Lock bytes** metric. You can see the overall percentage of Object Lock bytes for your account or organization.

5. To see the **% Object Lock bytes** per bucket, scroll down to the **Top N overview** section.

To get object-level data for Object Lock, you can also use the **Object Lock object count** and **% Object Lock objects** metrics.

6. For **Metric**, choose **% Object Lock bytes** from the **Data protection** category.

By default, the **Top N overview for date** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for date** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

Note

With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see [Metrics selection](#).

7. Review the following data for % Object Lock bytes:

- **Top *number* accounts** - See which accounts have the highest and lowest % Object Lock bytes.
- **Top *number* Regions** - View a breakdown of % Object Lock bytes by Region.
- **Top *number* buckets** - See which buckets have the highest and lowest % Object Lock bytes.

Using S3 Storage Lens to audit Object Ownership settings

Amazon S3 Object Ownership is an S3 bucket-level setting that you can use to disable access control lists (ACLs) and control ownership of the objects in your bucket. If you set Object Ownership to bucket owner enforced, you can disable [access control lists \(ACLs\)](#) and take ownership of every object in your bucket. This approach simplifies access management for data stored in Amazon S3.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through ACLs. You can use Object Ownership to change this default behavior.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. Therefore, we recommend that you disable ACLs, except in unusual circumstances where you must control access for each object individually. By setting Object Ownership to bucket owner enforced, you can disable ACLs and rely on policies for access control. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

With S3 Storage Lens access-management metrics, you can identify buckets that don't have disabled ACLs. After identifying these buckets, you can migrate ACL permissions to policies and disable ACLs for these buckets.

Topics

- [Step 1: Identify general trends for Object Ownership settings](#)
- [Step 2: Identify bucket-level trends for Object Ownership settings](#)

- [Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs](#)

Step 1: Identify general trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot for date** section, under **Metrics categories**, choose **Access management**.

The **Snapshot for date** section updates to display the **% Object Ownership bucket owner enforced** metric. You can see the overall percentage of buckets in your account or organization that use the bucket owner enforced setting for Object Ownership to disable ACLs.

Step 2: Identify bucket-level trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To view more detailed bucket-level metrics, choose the **Bucket** tab.
5. In the **Distribution by buckets for date** section, choose the **% Object Ownership bucket owner enforced** metric.

The chart updates to show a per-bucket breakdown for **% Object Ownership bucket owner enforced**. You can see which buckets use the bucket owner enforced setting for Object Ownership to disable ACLs.

6. To view the bucket owner enforced settings in context, scroll down to the **Buckets** section. For **Metrics categories**, select **Access management**. Then clear **Summary**.

The **Buckets** list displays data for all three Object Ownership settings: bucket owner enforced, bucket owner preferred, and object writer.

7. To filter the **Buckets** list to display metrics only for a specific Object Ownership setting, choose the preferences icon

).

8. Clear the metrics that you don't want to see.
9. (Optional) Under **Page size**, choose the number of buckets to display in the list.
10. Choose **Confirm**.

Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

After you've identified buckets that use the object writer and bucket owner preferred setting for Object Ownership, you can migrate your ACL permissions to bucket policies. When you've finished migrating your ACL permissions, you can then update your Object Ownership settings to bucket owner enforced in order to disable ACLs. For more information, see [Prerequisites for disabling ACLs](#).

Using S3 Storage Lens metrics to improve performance

If you have [S3 Storage Lens advanced metrics](#) enabled, you can use detailed status-code metrics to get counts for successful or failed requests. You can use this information to troubleshoot access or performance issues. Detailed status-code metrics show counts for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable. You can examine overall trends for detailed status-code metrics across S3 buckets, accounts, and organizations. Then, you can drill down into bucket-level metrics to identify workloads that are currently accessing these buckets and causing errors.

For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied. After you've identified these workloads, you can do a deep dive outside of S3 Storage Lens to troubleshoot your 403 Forbidden errors.

This example shows you how to do a trend analysis for the 403 Forbidden error by using the **403 Forbidden error count** and the **% 403 Forbidden errors** metrics. You can use these metrics to identify workloads that are accessing buckets without the correct permissions applied. You can do a similar trend analysis for any of the other **Detailed status code metrics**. For more information, see [Amazon S3 Storage Lens metrics glossary](#).

Prerequisite

To see **Detailed status code metrics** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Detailed status code metrics**. For more information, see [Using the S3 console](#).

Topics

- [Step 1: Do a trend analysis for an individual HTTP status code](#)
- [Step 2: Analyze error counts by bucket](#)
- [Step 3: Troubleshoot errors](#)

Step 1: Do a trend analysis for an individual HTTP status code

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, for **Primary metric**, choose **403 Forbidden error count** from the **Detailed status codes** category. For **Secondary metric**, choose **% 403 Forbidden errors**.
5. Scroll down to the **Top N overview for date** section. For **Metrics**, choose **403 Forbidden error count** or **% 403 Forbidden errors** from the **Detailed status codes** category.

The **Top N overview for date** section updates to display the top 403 Forbidden error counts by account, AWS Region, and bucket.

Step 2: Analyze error counts by bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Detailed status code** metrics. Then clear **Summary**.

The **Buckets** list updates to display all the available detailed status code metrics. You can use this information to see which buckets have a large proportion of certain HTTP status codes and which status codes are common across buckets.

6. To filter the **Buckets** list to display only specific detailed status-code metrics, choose the preferences icon

).

7. Clear the toggles for any detailed status-code metrics that you don't want to view in the **Buckets** list.
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list displays error count metrics for the number of buckets that you specified. You can use this information to identify specific buckets that are experiencing many errors and troubleshoot errors by bucket.

Step 3: Troubleshoot errors

After you identify buckets with a high proportion of specific HTTP status codes, you can troubleshoot these errors. For more information, see the following:

- [Why am I getting a 403 Forbidden error when I try to upload files in Amazon S3?](#)
- [Why am I getting a 403 Forbidden error when I try to modify a bucket policy in Amazon S3?](#)
- [How do I troubleshoot 403 Forbidden errors from my Amazon S3 bucket where all the resources are from the same AWS account?](#)
- [How do I troubleshoot an HTTP 500 or 503 error from Amazon S3?](#)

Using Amazon S3 Storage Lens with AWS Organizations

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use Amazon S3 Storage Lens to collect storage metrics and usage data for all AWS accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

After enabling trusted access, add delegated administrator access to accounts in your organization. The delegated administrator accounts are used to create S3 Storage Lens configurations and dashboards that collect organization-wide storage metrics and user data. For more information about enabling trusted access, see [Amazon S3 Storage Lens and AWS Organizations](#) in the *AWS Organizations User Guide*.

Topics

- [Enabling trusted access for S3 Storage Lens](#)
- [Disabling trusted access for S3 Storage Lens](#)
- [Registering a delegated administrator for S3 Storage Lens](#)
- [Deregistering a delegated administrator for S3 Storage Lens](#)

Enabling trusted access for S3 Storage Lens

By enabling trusted access, you allow Amazon S3 Storage Lens to access your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens then becomes a trusted service for your entire organization's structure.

Whenever a dashboard configuration is created, S3 Storage Lens creates service-linked roles in your organization's management or delegated administrator accounts. The service-linked role grants S3 Storage Lens permission to perform the following actions:

- Describe organizations
- List accounts
- Verify a list of AWS service access for the organizations
- Get delegated administrators for the organizations

S3 Storage Lens can then ensure that it has access to collect the cross-account metrics for the accounts in your organization. For more information, see [Using service-linked roles for Amazon S3 Storage Lens](#).

After enabling trusted access, you can assign delegated administrator access to accounts in your organization. When an account is marked as a delegated administrator for a service, the account receives authorization to access all read-only organization API operations. This access provides the delegated administrator visibility to the members and structures of your organization so that they too can create S3 Storage Lens dashboards.

 **Note**

- Trusted access can only be enabled by the [management account](#).
- Only the management account and delegated administrators can create S3 Storage Lens dashboards or configurations for your organization.

Using the S3 console

To enable S3 Storage Lens to have AWS Organizations trusted access

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

The **AWS Organizations access** page displays.

5. Choose **Enable** to enable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example shows you how to enable AWS Organizations trusted access for S3 Storage Lens in AWS CLI.

```
aws organizations enable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Enable AWS Organizations trusted access for S3 Storage Lens using SDK for Java

The following example shows you how to enable trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
```

```
import com.amazonaws.services.organizations.model.EnableAWSServiceAccessRequest;

public class EnableOrganizationsTrustedAccess {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.enableAWSServiceAccess(new
EnableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

Disabling trusted access for S3 Storage Lens

Removing an account as a delegated administrator or disabling trusted access limits the account owner's S3 Storage Lens dashboard metrics to work only on an account level. Each account holder is then only be able to see the benefits of S3 Storage Lens through the limited scope of their account, and not their entire organization.

When you disable trusted access in S3 Storage Lens, any dashboards requiring trusted access are no longer updated. Any organizational dashboards that are created are also no longer updated. Instead, you're only able to query [historic data for the S3 Storage Lens dashboard](#), while the data is still available.

Note

- Disabling trusted access for S3 Storage Lens also automatically stops all organization-level dashboards from collecting and aggregating storage metrics. This is because S3 Storage Lens no longer has trusted access to the organization accounts.
- Your management and delegate administrator accounts can still see the historic data for any disabled dashboards. They can also query this historic data while it is still available.

Using the S3 console

To disable trusted access for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

The **AWS Organizations access** page displays.

5. Choose **Disable** to disable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example disables trusted access for S3 Storage Lens using the AWS CLI.

```
aws organizations disable-aws-service-access --service-principal storage-lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Disable AWS Organizations trusted access for S3 Storage Lens

The following example shows you how to disable AWS Organizations trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.DisableAWSServiceAccessRequest;

public class DisableOrganizationsTrustedAccess {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            // Make sure to remove any existing delegated administrator for S3 Storage
            // Lens
            // before disabling access; otherwise, the request will fail.
            organizationsClient.disableAWSServiceAccess(new
DisableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
            process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

```
 }  
 }
```

Registering a delegated administrator for S3 Storage Lens

You can create organization-level dashboards by using your organization's management account or delegated administrator accounts. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can register and deregister other accounts as delegated administrators for the organization.

After enabling trusted access, you can register delegate administrator access to accounts in your organization by using the AWS Organizations REST API, AWS CLI, or SDKs from the [management account](#). (For more information, see [RegisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.) When an account is registered as a delegated administrator, the account receives authorization to access all read-only AWS Organizations API operations. This provides visibility to the members and structures of your organization so that they can create S3 Storage Lens dashboards on your behalf.

 **Note**

Before you can designate a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs, you must call the [EnableAWSOrganizationsAccess](#) operation.

Using the S3 console

To register delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose **Register account**.
5. Add an AWS account ID to register the account as a delegated administrator. The delegated administrator is able to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to register Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace the *user input placeholders* with your own information.

```
aws organizations register-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Register Organizations delegated administrators for S3 Storage Lens

The following example shows you how to register AWS Organizations delegated administrators for S3 Storage Lens in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.RegisterDelegatedAdministratorRequest;

public class RegisterOrganizationsDelegatedAdministrator {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.registerDelegatedAdministrator(new
RegisterDelegatedAdministratorRequest()
```

```
        .withAccountId(delegatedAdminAccountId)
        .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but AWS Organizations couldn't
        process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // AWS Organizations couldn't be contacted for a response, or the client
        // couldn't parse the response from AWS Organizations.
        e.printStackTrace();
    }
}
```

Deregistering a delegated administrator for S3 Storage Lens

After enabling trusted access, you can also deregister delegate administrator access to accounts in your organization. Delegated administrator accounts allow other accounts besides your [management account](#) to create organization-level dashboards. Only the management account of an organization can deregister accounts as delegated administrators for the organization.

You can deregister a delegated administrator by using the AWS Organizations AWS Management Console, REST API, AWS CLI, or AWS SDKs from the management account. For more information, see [DeregisterDelegatedAdministrator](#) in the *AWS Organizations API Reference*.

When an account is deregistered as a delegated administrator, the account loses access to the following:

- All read-only AWS Organizations API operations that provide visibility to the members and structures of your organization.
- All organization-level dashboards created by the delegated administrator. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

 **Note**

The deregistered delegated administrator will still be able to see the historic data for the disabled dashboards that they created if data is still available for querying.

Using the S3 console

To deregister delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose the account that you wish to deregister.
5. Choose **De-register account**. The deregistered account is no longer a delegated administrator and is now unable to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace **111122223333** with your own AWS account ID.

```
aws organizations deregister-delegated-administrator --service-principal storage-lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Deregister Organizations delegated administrators for S3 Storage Lens

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using SDK for Java. To use this example, replace the **user input placeholders** with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
```

```
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
com.amazonaws.services.organizations.model.DeregisterDelegatedAdministratorRequest;

public class DeregisterOrganizationsDelegatedAdministrator {
    private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

    public static void main(String[] args) {
        try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.deregisterDelegatedAdministrator(new
DeregisterDelegatedAdministratorRequest()
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
    }
}
```

Working with S3 Storage Lens groups to filter and aggregate metrics

An Amazon S3 Storage Lens group aggregates metrics using custom filters based on object metadata. Storage Lens groups help you drill down into characteristics of your data, such as distribution of objects by age, your most common file types, and more. For example, you can filter metrics by object tag to identify your fastest-growing datasets, or visualize your storage based on object size and age to inform your storage archive strategy. As a result, Amazon S3 Storage Lens groups helps you to better understand and optimize your S3 storage.

When you use Storage Lens groups, you can analyze and filter S3 Storage Lens metrics using object metadata such as prefixes, suffixes, [object tags](#), object size, or object age. You can also apply a combination of these filters. After you attach your Storage Lens group to your S3 Storage Lens dashboard, you can view S3 Storage Lens metrics aggregated by Amazon S3 Storage Lens groups directly in your dashboard.

For example, you can also filter your metrics by object size or age bands to determine which portion of your storage consists of small objects. You can then use this information with S3 Intelligent-Tiering or S3 Lifecycle to transition small objects to different storage classes for cost and storage optimization.

Topics

- [How S3 Storage Lens groups work](#)
- [Using Storage Lens groups](#)

How S3 Storage Lens groups work

You can use Storage Lens groups to aggregate metrics using custom filters based on object metadata. When you define a custom filter, you can use prefixes, suffixes, object tags, object sizes, object age, or a combination of these custom filters. During Storage Lens group creation, you can also include a single filter or multiple filter conditions. To specify multiple filter conditions, you use And or Or logical operators.

When you create and configure a Storage Lens group, the Storage Lens group itself acts as a custom filter in the dashboard that you attach the group to. In your dashboard, you can then use the Storage Lens group filter to obtain storage metrics based on the custom filter that you defined in the group.

To view the data for your Storage Lens group in your S3 Storage Lens dashboard, you must attach the group to the dashboard after you've created the group. After your Storage Lens group is attached to your Storage Lens dashboard, your dashboard will collect storage usage metrics within 48 hours. You can then visualize this data in the Storage Lens dashboard or export it through a metrics export. If you forget to attach a Storage Lens group to a dashboard, your Storage Lens group data won't be captured or displayed anywhere.

Note

- When you create a S3 Storage Lens group, you're creating an AWS resource. Therefore, each Storage Lens group has its own Amazon Resource Name (ARN), which you can specify when [attaching it to or excluding it from a S3 Storage Lens dashboard](#).
- If your Storage Lens group isn't attached to a dashboard, you won't incur any additional charges for creating a Storage Lens group.
- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.

You can create a Storage Lens group at the account level in a specified home Region (from the list of supported AWS Regions). Then, you can attach your Storage Lens group to multiple Storage Lens dashboards, as long as the dashboards are in the same AWS account and home Region. You can create up to 50 Storage Lens groups per home Region in each AWS account.

You can create and manage S3 Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API.

Topics

- [Viewing Storage Lens group aggregated metrics](#)
- [Storage Lens groups permissions](#)
- [Storage Lens groups configuration](#)
- [AWS resource tags](#)
- [Storage Lens groups metrics export](#)

Viewing Storage Lens group aggregated metrics

You can view the aggregated metrics for your Storage Lens groups by attaching the groups to a dashboard. The Storage Lens groups that you want to attach must reside within the designated home Region in the dashboard account.

To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of your dashboard configuration. If you have several Storage Lens

groups, you can filter the **Storage Lens group aggregation** results to include or exclude only the groups that you want. For more information about attaching groups to your dashboards, see [the section called "Attach or remove a Storage Lens group"](#).

After you've attached your groups, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

 **Note**

To view aggregated metrics for your Storage Lens group, you must attach the group to an S3 Storage Lens dashboard.

Storage Lens groups permissions

Storage Lens groups require certain permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens group actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to create or delete Storage Lens groups, view their configurations, or manage their tags.

The IAM user or role that you grant permissions to must belong to the account that created or owns the Storage Lens group.

To use Storage Lens groups and to view your Storage Lens groups metrics, you must first have the appropriate permissions to use S3 Storage Lens. For more information, see [the section called "Setting permissions"](#).

To create and manage S3 Storage Lens groups, you must have the following IAM permissions, depending on which actions you want to perform:

Action	IAM permissions
Create a new Storage Lens group	s3:CreateStorageLensGroup
Create a new Storage Lens group with tags	s3:CreateStorageLensGroup , s3:TagResource
Update an existing Storage Lens group	s3:UpdateStorageLensGroup

Action	IAM permissions
Return the details of a Storage Lens group configuration	s3:GetStorageLensGroup
List all Storage Lens groups in your home Region	s3>ListStorageLensGroups
Delete a Storage Lens group	s3>DeleteStorageLensGroup
List the tags that were added to your Storage Lens group	s3>ListTagsForResource
Add or update a Storage Lens group tag for an existing Storage Lens group	s3:TagResource
Delete a tag from a Storage Lens group	s3:UntagResource

Here's an example of how to configure your IAM policy in the account that creates the Storage Lens group. To use this policy, replace *us-east-1* with the home Region that your Storage Lens group is located in. Replace *111122223333* with your AWS account ID, and replace *example-storage-lens-group* with the name of your Storage Lens group. To apply these permissions to all Storage Lens groups, replace *example-storage-lens-group* with an *.

```

        "s3>DeleteStorageLensGroup",
        "s3:TagResource",
        "s3:UntagResource",
        "s3>ListTagsForResource"
      ],
    }
  ]
}
```

```
"Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens-group/example-storage-lens-group"  
}  
]  
}
```

For more information about S3 Storage Lens permissions, see [Setting Amazon S3 Storage Lens permissions](#). For more information about IAM policy language, see [Policies and permissions in Amazon S3](#).

Storage Lens groups configuration

S3 Storage Lens group name

We recommend giving your Storage Lens groups names that indicate their purpose so that you can easily determine which groups you want to attach to your dashboards. To [attach a Storage Lens group to a dashboard](#), you must specify the group in the **Storage Lens group aggregation** section of the dashboard configuration.

Storage Lens group names must be unique within the account. They must not exceed 64 characters, and can contain only letters (a-z, A-Z), numbers (0-9), hyphens (-), and underscores (_).

Home Region

The home Region is the AWS Region where your Storage Lens group is created and maintained. Your Storage Lens group is created in the same home Region as your Amazon S3 Storage Lens dashboard. The Storage Lens group configuration and metrics are also stored in this Region. You can create up to 50 Storage Lens groups in a home Region.

After you create your Storage Lens group, you can't edit the home Region.

Scope

To include objects in your Storage Lens group, they must be in scope for your Amazon S3 Storage Lens dashboard. The scope of your Storage Lens dashboard is determined by the buckets that you included in the **Dashboard scope** of your S3 Storage Lens dashboard configuration.

You can use different filters for your objects to define the scope of your Storage Lens group. To view these Storage Lens group metrics in your S3 Storage Lens dashboard, objects must match the filters that you include in your Storage Lens groups. For example, suppose that your Storage Lens

group includes objects with the prefix `marketing` and the suffix `.png`, but no objects match those criteria. In this case, metrics for this Storage Lens group won't be generated in your daily metrics export, and no metrics for this group will be visible in your dashboard.

Filters

You can use the following filters in an S3 Storage Lens group:

- **Prefixes** – Specifies the [prefix](#) of included objects, which is a string of characters at the beginning of the object key name. For example, a value of `images` for the **Prefixes** filter includes objects with any of the following prefixes: `images/`, `images-marketing`, and `images/production`. The maximum length of a prefix is 1,024 bytes.
- **Suffixes** – Specifies the suffix of included objects (for example, `.png`, `.jpeg`, or `.csv`). The maximum length of a suffix is 1,024 bytes.
- **Object tags** – Specifies the list of [object tags](#) that you want to filter on. A tag key can't exceed 128 Unicode characters, and a tag value can't exceed 256 Unicode characters. Note that if the object tag value field is left empty, S3 Storage Lens groups only matches the object to other objects that also have empty tag values.
- **Age** – Specifies the object age range of included objects in days. Only integers are supported.
- **Size** – Specifies the object size range of included objects in bytes. Only integers are supported. The maximum allowable value is 5 TB.

Storage Lens group object tags

You can [create a Storage Lens group](#) that includes up to 10 object tag filters. The following example includes two object tag key-value pairs as filters for a Storage Lens group that's named `Marketing-Department`. To use this example, replace `Marketing-Department` with the name of your group, and replace `object-tag-key-1`, `object-tag-value-1`, and so on with the object tag key-value pairs that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "MatchAnyTag": [  
            {  
                "Key": "object-tag-key-1",  
                "Value": "object-tag-value-1"  
            },  
        ]  
    }  
}
```

```
{  
    "Key": "object-tag-key-2",  
    "Value": "object-tag-value-2"  
}  
]  
}  
}
```

Logical operators (And or Or)

To include multiple filter conditions in your Storage Lens group, you can use logical operators (either And or Or). In the following example, the Storage Lens group that's named *Marketing-Department* has an And operator that contains Prefix, ObjectAge, and ObjectSize filters. Because an And operator is used, only objects that match **all** of these filter conditions will be included the Storage Lens group's scope.

To use this example, replace the *user input placeholders* with the values that you want to filter on.

```
{  
    "Name": "Marketing-Department",  
    "Filter": {  
        "And": {  
            "MatchAnyPrefix": [  
                "prefix-1",  
                "prefix-2",  
                "prefix-3/sub-prefix-1"  
            ],  
            "MatchObjectAge": {  
                "DaysGreaterThanOrEqual": 10,  
                "DaysLessThanOrEqual": 60  
            },  
            "MatchObjectSize": {  
                "BytesGreaterThanOrEqual": 10,  
                "BytesLessThanOrEqual": 60  
            }  
        }  
    }  
}
```

Note

If you want to include objects that match **any** of the conditions in the filters, replace the And logical operator with the Or logical operator in this example.

AWS resource tags

Each S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (or tags with tag keys that begin with `aws :)`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

Storage Lens groups metrics export

S3 Storage Lens group metrics are included in the [Amazon S3 Storage Lens metrics export](#) for the dashboard that the Storage Lens group is attached to. For general information about the Storage Lens metrics export feature, see [Viewing Amazon S3 Storage Lens metrics using a data export](#).

Your metrics export for Storage Lens groups includes any S3 Storage Lens metrics that are in scope for the dashboard that you attached the Storage Lens group to. The export also includes additional metrics data for Storage Lens groups.

After you create your Storage Lens group, your metrics export is sent daily to the bucket that you selected when you configured the metrics export for the dashboard that your group is attached to. It can take up to 48 hours for you to receive the first metrics export.

To generate metrics in the daily export, objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you included in your Storage Lens group, then no metrics will be generated. However, if an object matches two or more Storage Lens groups, the object is listed separately for each group when it appears in the metrics export.

You can identify metrics for Storage Lens groups by looking for one of the following values in the `record_type` column of the metrics export for your dashboard:

- `STORAGE_LENS_GROUP_BUCKET`
- `STORAGE_LENS_GROUP_ACCOUNT`

The `record_value` column displays the resource ARN for the Storage Lens group (for example, `arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department`).

Using Storage Lens groups

Amazon S3 Storage Lens groups aggregates metrics using custom filters based on object metadata. You can analyze and filter S3 Storage Lens metrics using prefixes, suffixes, object tags, object size, or object age. With Amazon S3 Storage Lens groups, you can also categorize your usage within and across Amazon S3 buckets. As a result, you'll be able to better understand and optimize your S3 storage.

To start visualizing the data for a Storage Lens group, you must first [attach your Storage Lens group to an S3 Storage Lens dashboard](#). If you need to manage Storage Lens groups in the dashboard, you can edit the dashboard configuration. To check which Storage Lens groups are

under your account, you can list them. To check which Storage Lens groups are attached to your dashboard, you can always check the **Storage Lens groups** tab in the dashboard. To review or update the scope of an existing Storage Lens group, you can view its details. You can also permanently delete a Storage Lens group.

To manage permissions, you can create and add user-defined AWS resource tags to your Storage Lens groups. You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

Creating a Storage Lens group

The following examples demonstrate how to create an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To create a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Storage Lens groups**.
4. Choose **Create Storage Lens group**.
5. Under **General**, view your **Home Region** and enter your **Storage Lens group name**.
6. Under **Scope**, choose the filter that you want to apply to your Storage Lens group. To apply multiple filters, choose your filters, and then choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, choose **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, choose **Object tags**, and enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, choose **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. Then, choose **Specify maximum object age**, and enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. Choose **Specify maximum object size**, and enter the maximum object size.
7. (Optional) For AWS resource tags, add the key-value pair, and then choose **Add tag**.
8. Choose **Create Storage Lens group**.

Using the AWS CLI

The following example AWS CLI command creates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

The following example AWS CLI command creates a Storage Lens group with two AWS resource tags. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json \
--tags Key=k1,Value=v1 Key=k2,Value=v2
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example creates a Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

Example – Create a Storage Lens group with a single filter

The following example creates a Storage Lens group named *Marketing-Department*. This group has an object age filter that specifies the age range as *30* to *90* days. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithObjectAge {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupFilter objectAgeFilter = StorageLensGroupFilter.builder()
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreaterThanOrEqualTo(30)
                    .daysLessThanOrEqualTo(90)
```

```
        .build())
    .build();

    StorageLensGroup storageLensGroup = StorageLensGroup.builder()
        .name(storageLensGroupName)
        .filter(objectAgeFilter)
        .build();

    CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with an AND operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses the AND operator to indicate that objects must match **all** of the filter conditions. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.S3Tag;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupAndOperator;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithAndFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create object tags.
            S3Tag tag1 = S3Tag.builder()
                .key("object-tag-key-1")
                .value("object-tag-value-1")
                .build();
            S3Tag tag2 = S3Tag.builder()
                .key("object-tag-key-2")
                .value("object-tag-value-2")
                .build();

            StorageLensGroupAndOperator andOperator =
            StorageLensGroupAndOperator.builder()
                .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                .matchAnySuffix(".png", ".gif", ".jpg")
                .matchAnyTag(tag1, tag2)
                .matchObjectAge(MatchObjectAge.builder()
                    .daysGreater Than(30)
                    .daysLessThan(90).build())
                .matchObjectSize(MatchObjectSize.builder()
                    .bytesGreater Than(1000L)
                    .bytesLessThan(6000L).build())
                .build();

            StorageLensGroupFilter andFilter = StorageLensGroupFilter.builder()
                .and(andOperator)
                .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                .name(storageLensGroupName)
```

```
        .filter(andFilter)
        .build();

    CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
        .storageLensGroup(storageLensGroup)
        .accountId(accountId).build();

    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Create a Storage Lens group with an OR operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses an OR operator to apply a prefix filter (*prefix-1*, *prefix-2*, *prefix3*/*sub-prefix-1*) or an object size filter with a size range between *1000* bytes and *6000* bytes. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
```

```
import software.amazon.awssdk.services.s3control.model.StorageLensGroupOrOperator;

public class CreateStorageLensGroupWithOrFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupOrOperator orOperator =
                StorageLensGroupOrOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchObjectSize(MatchObjectSize.builder()
                        .bytesGreaterThan(1000L)
                        .bytesLessThan(6000L)
                        .build())
                    .build();
        }

        StorageLensGroupFilter orFilter = StorageLensGroupFilter.builder()
            .or(orOperator)
            .build();

        StorageLensGroup storageLensGroup = StorageLensGroup.builder()
            .name(storageLensGroupName)
            .filter(orFilter)
            .build();

        CreateStorageLensGroupRequest createStorageLensGroupRequest =
            CreateStorageLensGroupRequest.builder()
                .storageLensGroup(storageLensGroup)
                .accountId(accountId).build();

        S3ControlClient s3ControlClient = S3ControlClient.builder()
            .region(Region.US_WEST_2)
            .credentialsProvider(ProfileCredentialsProvider.create())
            .build();
        s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
```

```
    }  
}  
}
```

Example – Create a Storage Lens group with a single filter and two AWS resource tags

The following example creates a Storage Lens group named *Marketing-Department* that has a suffix filter. This example also adds two AWS resource tags to the Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;  
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;  
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;  
import software.amazon.awssdk.services.s3control.model.Tag;  
  
public class CreateStorageLensGroupWithResourceTags {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            // Create AWS resource tags.  
            Tag resourceTag1 = Tag.builder()  
                .key("resource-tag-key-1")  
                .value("resource-tag-value-1")  
                .build();  
            Tag resourceTag2 = Tag.builder()  
                .key("resource-tag-key-2")  
                .value("resource-tag-value-2")  
                .build();  
  
            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()  
                .matchAnySuffix(".png", ".gif", ".jpg")  
                .build();  
  
            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
```

```
.name(storageLensGroupName)
.filter(suffixFilter)
.build();

CreateStorageLensGroupRequest createStorageLensGroupRequest =
CreateStorageLensGroupRequest.builder()
    .storageLensGroup(storageLensGroup)
    .tags(resourceTag1, resourceTag2)
    .accountId(accountId).build();

S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();
s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Attaching or removing S3 Storage Lens groups to or from your dashboard

After you've upgraded to the advanced tier in Amazon S3 Storage Lens, you can attach a [Storage Lens group](#) to your dashboard. If you have several Storage Lens groups, you can include or exclude the groups that you want.

Your Storage Lens groups must reside within the designated home Region in the dashboard account. After you attach a Storage Lens group to your dashboard, you'll receive the additional Storage Lens group aggregation data in your metrics export within 48 hours.

Note

If you want to view aggregated metrics for your Storage Lens group, you must attach it to your Storage Lens dashboard. For examples of Storage Lens group JSON configuration files, see [S3 Storage Lens example configuration with Storage Lens groups in JSON](#).

Using the S3 console

To attach a Storage Lens group to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to attach a Storage Lens group to.
4. Choose **Edit**.
5. Under **Metrics selection**, choose **Advanced metrics and recommendations**.
6. Select **Storage Lens group aggregation**.

Note

By default, **Advanced metrics** is also selected. However, you can also deselect this setting as it's not required to aggregate Storage Lens groups data.

7. Scroll down to **Storage Lens group aggregation** and specify the Storage Lens group or groups that you either want to include or exclude in the data aggregation. You can use the following filtering options:
 - If you want to include certain Storage Lens groups, choose **Include Storage Lens groups**. Under **Storage Lens groups to include**, select your Storage Lens groups.
 - If you want to include all Storage Lens groups, select **Include all Storage Lens groups in home Region in this account**.
 - If you want to exclude certain Storage Lens groups, choose **Exclude Storage Lens groups**. Under **Storage Lens groups to exclude**, select the Storage Lens groups that you want to exclude.

8. Choose **Save changes**. If you've configured your Storage Lens groups correctly, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

To remove a Storage Lens group from an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to remove a Storage Lens group from.
4. Choose **View dashboard configuration**.
5. Choose **Edit**.
6. Scroll down to the **Metrics selection** section.
7. Under **Storage Lens group aggregation**, choose the X next to the Storage Lens group that you want to remove. This removes your Storage Lens group.

If you included all of your Storage Lens groups in your dashboard, clear the check box next to **Include all Storage Lens groups in home Region in this account**.

8. Choose **Save changes**.

 **Note**

It will take up to 48 hours for your dashboard to reflect the configuration updates.

Using the AWS SDK for Java

Example – Attach all Storage Lens groups to a dashboard

The following SDK for Java example attaches all Storage Lens groups in the account **111122223333** to the **DashboardConfigurationId** dashboard:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3control.AWS3Control;
```

```
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWithStorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel();

            AccountLevel accountLevel = new AccountLevel()
                .withBucketLevel(new BucketLevel())
                .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
                .withAccountLevel(accountLevel)
                .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

            s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
```

```
        // couldn't parse the response from Amazon S3.  
        e.printStackTrace();  
    }  
}  
}
```

Example – Attach two Storage Lens groups to a dashboard

The following AWS SDK for Java example attaches two Storage Lens groups (*StorageLensGroupName1* and *StorageLensGroupName2*) to the *ExampleDashboardConfigurationId* dashboard.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import com.amazonaws.auth.profile.ProfileCredentialsProvider;  
import com.amazonaws.services.s3control.AWSS3Control;  
import com.amazonaws.services.s3control.AWSS3ControlClient;  
import com.amazonaws.services.s3control.model.AccountLevel;  
import com.amazonaws.services.s3control.model.BucketLevel;  
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;  
import com.amazonaws.services.s3control.model.StorageLensConfiguration;  
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;  
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;  
  
import static com.amazonaws.regions.Regions.US_WEST_2;  
  
public class CreateDashboardWith2StorageLensGroups {  
    public static void main(String[] args) {  
        String configurationId = "ExampleDashboardConfigurationId";  
        String storageLensGroupName1 = "StorageLensGroupName1";  
        String storageLensGroupName2 = "StorageLensGroupName2";  
        String sourceAccountId = "111122223333";  
  
        try {  
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new  
            StorageLensGroupLevelSelectionCriteria()  
                .withInclude(  
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId  
+ ":storage-lens-group/" + storageLensGroupName1,  
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId  
+ ":storage-lens-group/" + storageLensGroupName2);  
        }  
    }  
}
```

```
System.out.println(selectionCriteria);
StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
    .withSelectionCriteria(selectionCriteria);

AccountLevel accountLevel = new AccountLevel()
    .withBucketLevel(new BucketLevel())
    .withStorageLensGroupLevel(storageLensGroupLevel);

StorageLensConfiguration configuration = new StorageLensConfiguration()
    .withId(configurationId)
    .withAccountLevel(accountLevel)
    .withIsEnabled(true);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();

s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
);

} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Example – Attach all Storage Lens groups with exclusions

The following SDK for Java example attaches all Storage Lens groups to the *ExampleDashboardConfigurationId* dashboard, excluding the two specified (*StorageLensGroupName1* and *StorageLensGroupName2*):

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroupsExcluded {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
            StorageLensGroupLevelSelectionCriteria()
                .withInclude(
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName1,
                    "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensLevel = new StorageLensGroupLevel()
                .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                .withBucketLevel(new BucketLevel())
                .withStorageLensGroupLevel(storageLensLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
```

```
.withAccountLevel(accountLevel)
.withIsEnabled(true);

AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
    .withCredentials(new ProfileCredentialsProvider())
    .withRegion(US_WEST_2)
    .build();

s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
    .withAccountId(sourceAccountId)
    .withConfigId(configurationId)
    .withStorageLensConfiguration(configuration)
);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
}
```

Visualizing your Storage Lens groups data

You can visualize your Storage Lens groups data by [attaching the group to your Amazon S3 Storage Lens dashboard](#). After you've included the Storage Lens group in the Storage Lens group aggregation in your dashboard configuration, it can take up to 48 hours for the Storage Lens group data to display in your dashboard.

After the dashboard configuration has been updated, any newly attached Storage Lens groups appear in the list of available resources under the **Storage Lens groups** tab. You can also further analyze storage usage in your **Overview** tab by slicing the data by another dimension. For example, you can choose one of the items listed under the **Top 3** categories and choose **Analyze by** to slice the data by another dimension. You can't apply the same dimension as the filter itself.

Note

You can't apply a Storage Lens group filter along with a prefix filter, or the reverse. You also can't further analyze a Storage Lens group by using a prefix filter.

You can use the **Storage Lens groups** tab in the Amazon S3 Storage Lens dashboard to customize the data visualization for the Storage Lens groups that are attached to your dashboard. You can either visualize the data for some Storage Lens groups that are attached to your dashboard, or all of them.

When visualizing Storage Lens group data in your S3 Storage Lens dashboard, be aware of the following:

- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.
- Objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you include in your Storage Lens group, then no metrics are generated. To determine if there are any unassigned objects, check your total object count in the dashboard at the account level and bucket level.

Updating a Storage Lens group

The following examples demonstrate how to update an Amazon S3 Storage Lens group. You can update a Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **Scope**, choose **Edit**.

5. On the **Scope** page, select the filter that you want to apply to your Storage Lens group. To apply multiple filters, select your filters, and choose the **AND** or **OR** logical operator.
 - For the **Prefixes** filter, select **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
 - For the **Object tags** filter, enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
 - For the **Suffixes** filter, select **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
 - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. For **Specify maximum object age**, enter the maximum object age.
 - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. For **Specify maximum object size**, enter the maximum object size.
6. Choose **Save changes**. The details page for the Storage Lens group appears.
7. (Optional) If you want to add a new AWS resource tag, scroll to the **AWS resource tags** section, then choose **Add tags**. The **Add tags** page appears.

Add the new key-value pair, then choose **Save changes**. The details page for the Storage Lens group appears.

8. (Optional) If you want to remove an existing AWS resource tag, scroll to the **AWS resource tags** section, and select the resource tag. Then, choose **Delete**. The **Delete AWS tags** dialog box appears.

Choose **Delete** again to permanently delete the AWS resource tag.

 **Note**

After you permanently delete an AWS resource tag, it can't be restored.

Using the AWS CLI

The following AWS CLI example command returns the configuration details for a Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

The following AWS CLI example updates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control update-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the *Marketing-Department* Storage Lens group in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
GetStorageLensGroupRequest.builder()
```

```
        .name(storageLensGroupName)
        .accountId(accountId).build();
    S3ControlClient s3ControlClient = S3ControlClient.builder()
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

The following example updates the Storage Lens group named *Marketing-Department* in account *111122223333*. This example updates the dashboard scope to include objects that match any of the following suffixes: *.png*, *.gif*, *.jpg*, or *.jpeg*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.UpdateStorageLensGroupRequest;

public class UpdateStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
// Create updated filter.
StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
    .matchAnySuffix(".png", ".gif", ".jpg", ".jpeg")
    .build();

StorageLensGroup storageLensGroup = StorageLensGroup.builder()
    .name(storageLensGroupName)
    .filter(suffixFilter)
    .build();

UpdateStorageLensGroupRequest updateStorageLensGroupRequest =
UpdateStorageLensGroupRequest.builder()
    .name(storageLensGroupName)
    .storageLensGroup(storageLensGroup)
    .accountId(accountId)
    .build();

S3ControlClient s3ControlClient = S3ControlClient.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();
s3ControlClient.updateStorageLensGroup(updateStorageLensGroupRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

For example JSON configurations, see [Storage Lens groups configuration](#).

Managing AWS resource tags with Storage Lens groups

Each Amazon S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate [attribute-based access control \(ABAC\)](#). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to [control access to AWS resources](#).

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with aws :) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens groups.

Topics

Adding an AWS resource tag to a Storage Lens group

The following examples demonstrate how to add AWS resource tags to an Amazon S3 Storage Lens group. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add an AWS resource tag to a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, choose **Add tags**.
5. On the **Add tags** page, add the new key-value pair.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens group.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command adds two resource tags to an existing Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1 --tags Key=k1,Value=v1 Key=k2,Value=v2
```

Using the AWS SDK for Java

The following AWS SDK for Java example adds two AWS resource tags to an existing Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class TagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                .key("resource-tag-key-2")
                .value("resource-tag-value-2")
                .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tags(resourceTag1, resourceTag2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

```
}
```

Updating Storage Lens group tag values

The following examples demonstrate how to update Storage Lens group tag values by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the tag that you want to update.
5. Add the new tag value, using the same key of the key-value pair that you want to update. Choose the checkmark icon to update the tag value.

 **Note**

Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) If you want to add new tags, choose **Add tag** to add new entries. The **Add tags** page appears.

You can add up to 50 AWS resource tags for your Storage Lens group. When you're finished adding new tags, choose **Save changes**.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove. When you're finished removing tags, choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command updates two tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \  
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-department \  
--region us-east-1 --tags Key=k1,Value=v3 Key=k2,Value=v4
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates two Storage Lens group tag values. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.Tag;  
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;  
  
public class UpdateTagsForResource {  
    public static void main(String[] args) {  
        String resourceARN = "Resource_ARN";  
        String accountId = "111122223333";  
  
        try {  
            Tag updatedResourceTag1 = Tag.builder()  
                .key("resource-tag-key-1")  
                .value("resource-tag-updated-value-1")  
                .build();  
            Tag updatedResourceTag2 = Tag.builder()  
                .key("resource-tag-key-2")  
                .value("resource-tag-updated-value-2")  
                .build();  
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()  
                .resourceArn(resourceARN)  
                .tags(updatedResourceTag1, updatedResourceTag2)  
                .accountId(accountId)  
                .build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()  
                .region(Region.US_WEST_2)  
                .credentialsProvider(ProfileCredentialsProvider.create())  
                .build();  
        } catch (AmazonServiceException | SdkClientException e) {  
            System.out.println(e.getMessage());  
        }  
    }  
}
```

```
s3ControlClient.tagResource(tagResourceRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting an AWS resource tag from a Storage Lens group

The following examples demonstrate how to delete an AWS resource tag from a Storage Lens group. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete an AWS resource tag from a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the key-value pair that you want to delete.
5. Choose **Delete**. The **Delete AWS resource tags** dialog box appears.

 **Note**

If tags are used to control access, proceeding with this action can affect related resources. After you permanently delete a tag, it can't be restored.

6. Choose **Delete** to permanently delete the key-value pair.

Using the AWS CLI

The following AWS CLI command deletes two AWS resource tags from an existing Storage Lens group: To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control untag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department \
--region us-east-1 --tag-keys k1 k2
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes two AWS resource tags from the Storage Lens group Amazon Resource Name (ARN) that you specify in account **111122223333**. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;

public class UntagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            String tagKey1 = "resource-tag-key-1";
            String tagKey2 = "resource-tag-key-2";
            UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                .resourceArn(resourceARN)
                .tagKeys(tagKey1, tagKey2)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
        }
    }
}
```

```
        .build();
    s3ControlClient.untagResource(untagResourceRequest);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Listing Storage Lens group tags

The following examples demonstrate how to list the AWS resource tags associated with a Storage Lens group. You can list tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To review the list of tags and tag values for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you're interested in.
4. Scroll down to the **AWS resource tags** section. All of the user-defined AWS resource tags that are added to your Storage Lens group are listed along with their tag values.

Using the AWS CLI

The following AWS CLI example command lists all the Storage Lens group tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-tags-for-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
```

```
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens group tag values for the Storage Lens group Amazon Resource Name (ARN) that you specify. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                .resourceArn(resourceARN)
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListTagsForResourceResponse response =
s3ControlClient.listTagsForResource(listTagsForResourceRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
        }
    }
}
```

```
        e.printStackTrace();
    }
}
}
```

Listing all Storage Lens groups

The following examples demonstrate how to list all Amazon S3 Storage Lens groups in an AWS account and home Region. These examples show how list all Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To list all Storage Lens groups in an account and home Region

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, the list of Storage Lens groups in your account is displayed.

Using the AWS CLI

The following AWS CLI example lists all of the Storage Lens groups for your account. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-groups --account-id 111122223333 \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens groups for account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
```

```
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsRequest;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsResponse;

public class ListStorageLensGroups {
    public static void main(String[] args) {
        String accountId = "111122223333";

        try {
            ListStorageLensGroupsRequest listStorageLensGroupsRequest =
ListStorageLensGroupsRequest.builder()
                .accountId(accountId)
                .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                .region(Region.US_WEST_2)
                .credentialsProvider(ProfileCredentialsProvider.create())
                .build();
            ListStorageLensGroupsResponse response =
s3ControlClient.listStorageLensGroups(listStorageLensGroupsRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Viewing Storage Lens group details

The following examples demonstrate how to view Amazon S3 Storage Lens group configuration details. You can view these details by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To view Storage Lens group configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you're interested in.
4. Choose **View details**. You can now review the details of your Storage Lens group.

Using the AWS CLI

The following AWS CLI example returns the configuration details for a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;  
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;  
  
public class GetStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            GetStorageLensGroupRequest getRequest =  
GetStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()
```

```
        .region(Region.US_WEST_2)
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();
    GetStorageLensGroupResponse response =
s3ControlClient.getStorageLensGroup(getRequest);
    System.out.println(response);
} catch (AmazonServiceException e) {
    // The call was transmitted successfully, but Amazon S3 couldn't process
    // it and returned an error response.
    e.printStackTrace();
} catch (SdkClientException e) {
    // Amazon S3 couldn't be contacted for a response, or the client
    // couldn't parse the response from Amazon S3.
    e.printStackTrace();
}
}
```

Deleting a Storage Lens group

The following examples demonstrate how to delete an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you want to delete.
4. Choose **Delete**. A **Delete Storage Lens group** dialog box displays.
5. Choose **Delete** again to permanently delete your Storage Lens group.

Note

After you delete a Storage Lens group, it can't be restored.

Using the AWS CLI

The following AWS CLI example deletes the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-group --account-id 111122223333 \  
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;  
  
import com.amazonaws.AmazonServiceException;  
import com.amazonaws.SdkClientException;  
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;  
import software.amazon.awssdk.regions.Region;  
import software.amazon.awssdk.services.s3control.S3ControlClient;  
import software.amazon.awssdk.services.s3control.model.DeleteStorageLensGroupRequest;  
  
public class DeleteStorageLensGroup {  
    public static void main(String[] args) {  
        String storageLensGroupName = "Marketing-Department";  
        String accountId = "111122223333";  
  
        try {  
            DeleteStorageLensGroupRequest deleteStorageLensGroupRequest =  
DeleteStorageLensGroupRequest.builder()  
                .name(storageLensGroupName)  
                .accountId(accountId).build();  
            S3ControlClient s3ControlClient = S3ControlClient.builder()  
                .region(Region.US_WEST_2)  
                .credentialsProvider(ProfileCredentialsProvider.create())  
                .build();  
            s3ControlClient.deleteStorageLensGroup(deleteStorageLensGroupRequest);  
        } catch (AmazonServiceException e) {  
            // The call was transmitted successfully, but Amazon S3 couldn't process  
            // it and returned an error response.  
        }  
    }  
}
```

```
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}
}
```

Cataloging and analyzing your data with S3 Inventory

You can use Amazon S3 Inventory to help manage your storage. For example, you can use it to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also simplify and speed up business workflows and big data jobs by using Amazon S3 Inventory, which provides a scheduled alternative to the Amazon S3 synchronous List API operations. Amazon S3 Inventory does not use the List API operations to audit your objects and does not affect the request rate of your bucket.

Amazon S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#) or [Apache Parquet](#) output files that list your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or objects with a shared prefix (that is, objects that have names that begin with a common string). If you set up a weekly inventory, a report is generated every Sunday (UTC time zone) after the initial report. For information about Amazon S3 Inventory pricing, see [Amazon S3 pricing](#).

You can configure multiple inventory lists for a bucket. When you're configuring an inventory list, you can specify the following:

- What object metadata to include in the inventory
- Whether to list all object versions or only current versions
- Where to store the inventory list file output
- Whether to generate the inventory on a daily or weekly basis
- Whether to encrypt the inventory list file

You can query Amazon S3 Inventory with standard SQL queries by using [Amazon Athena](#), [Amazon Redshift Spectrum](#), and other tools, such as [Presto](#), [Apache Hive](#), and [Apache Spark](#). For more information about using Athena to query your inventory files, see [the section called “Querying inventory with Athena”](#).

Note

It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

Source and destination buckets

The bucket that the inventory lists objects for is called the *source bucket*. The bucket where the inventory list file is stored is called the *destination bucket*.

Source bucket

The inventory lists the objects that are stored in the source bucket. You can get an inventory list for an entire bucket, or you can filter the list by object key name prefix.

The source bucket:

- Contains the objects that are listed in the inventory
- Contains the configuration for the inventory

Destination bucket

Amazon S3 Inventory list files are written to the destination bucket. To group all the inventory list files in a common location in the destination bucket, you can specify a destination prefix in the inventory configuration.

The destination bucket:

- Contains the inventory file lists.
- Contains the manifest files that list all the inventory list files that are stored in the destination bucket. For more information, see [Inventory manifest](#).
- Must have a bucket policy to give Amazon S3 permission to verify ownership of the bucket and permission to write files to the bucket.
- Must be in the same AWS Region as the source bucket.
- Can be the same as the source bucket.
- Can be owned by a different AWS account than the account that owns the source bucket.

Amazon S3 Inventory list

An inventory list file contains a list of the objects in the source bucket and metadata for each object. An inventory list file is stored in the destination bucket with one of the following formats:

- As a CSV file compressed with GZIP
- As an Apache optimized row columnar (ORC) file compressed with ZLIB
- As an Apache Parquet file compressed with Snappy

 **Note**

Objects in Amazon S3 Inventory reports aren't guaranteed to be sorted in any order.

An inventory list file contains a list of the objects in the source bucket and metadata for each listed object:

- **Bucket name** – The name of the bucket that the inventory is for.
- **Key name** – The object key name (or key) that uniquely identifies the object in the bucket. When you're using the CSV file format, the key name is URL-encoded and must be decoded before you can use it.
- **Version ID** – The object version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see [Retaining multiple versions of objects with S3 Versioning](#). (This field is not included if the list is configured only for the current version of the objects.)
- **IsLatest** – Set to True if the object is the current version of the object. (This field is not included if the list is configured only for the current version of the objects.)
- **Delete marker** – Set to True if the object is a delete marker. For more information, see [Retaining multiple versions of objects with S3 Versioning](#). (This field is automatically added to your report if you've configured the report to include all versions of your objects).
- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object

data. Whether it is depends on how the object was created and how it is encrypted. For more information, see [Object](#) in the *Amazon Simple Storage Service API Reference*.

- **Storage class** – The storage class that's used for storing the object. Set to STANDARD, REDUCED_REDUNDANCY, STANDARD_IA, ONEZONE_IA, INTELLIGENT_TIERING, GLACIER, DEEP_ARCHIVE, OUTPOSTS, GLACIER_IR, or SNOW. For more information, see [Understanding and managing Amazon S3 storage classes](#).

 **Note**

S3 Inventory does not support S3 Express One Zone.

- **Multipart upload flag** – Set to True if the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).
- **Replication status** – Set to PENDING, COMPLETED, FAILED, or REPLICA. For more information, see [Getting replication status information](#).
- **Encryption status** – The server-side encryption status, depending on what kind of encryption key is used—server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). Set to SSE-S3, SSE-KMS, DSSE-KMS, SSE-C, or NOT-SSE. A status of NOT-SSE means that the object is not encrypted with server-side encryption. For more information, see [Protecting data with encryption](#).
- **S3 Object Lock retain until date** – The date until which the locked object cannot be deleted. For more information, see [Locking objects with Object Lock](#).
- **S3 Object Lock retention mode** – Set to Governance or Compliance for objects that are locked. For more information, see [Locking objects with Object Lock](#).
- **S3 Object Lock legal hold status** – Set to On if a legal hold has been applied to an object. Otherwise, it is set to Off. For more information, see [Locking objects with Object Lock](#).
- **S3 Intelligent-Tiering access tier** – Access tier (frequent or infrequent) of the object if it is stored in the S3 Intelligent-Tiering storage class. Set to FREQUENT, INFREQUENT, ARCHIVE_INSTANT_ACCESS, ARCHIVE, or DEEP_ARCHIVE. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **S3 Bucket Key status** – Set to ENABLED or DISABLED. Indicates whether the object uses an S3 Bucket Key for SSE-KMS. For more information, see [Using Amazon S3 Bucket Keys](#).

- **Checksum algorithm** – Indicates the algorithm that's used to create the checksum for the object. For more information, see [Using supported checksum algorithms](#).
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. The Object ACL field is defined in JSON format. An S3 Inventory report includes ACLs that are associated with objects in your source bucket, even when ACLs are disabled for the bucket. For more information, see [Working with the Object ACL field](#) and [Access control list \(ACL\) overview](#).

 **Note**

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {"canonicalId": "example-canonical-user-ID",  
         "type": "CanonicalUser",  
         "permission": "READ"  
     ]  
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2Fs
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

- **Object owner** – The canonical user ID of the owner of the object. For more information, see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

Note

When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. The inventory report includes the objects that have expired but haven't been removed yet. For more information about expiration actions in S3 Lifecycle, see [Expiring objects](#).

The following is an example inventory report with additional metadata fields consisting of four records.

```
amzn-s3-demo-bucket1    example-object-1    EXAMPLEDC81.XJCEN1F7LePaNIIvs001    TRUE

```

We recommend that you create a lifecycle policy that deletes old inventory lists. For more information, see [Managing the lifecycle of objects](#).

The `s3:PutInventoryConfiguration` permission allows a user to both select all the metadata fields that are listed earlier for each object when configuring an inventory list and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory list. To restrict access to an inventory report, see [Grant permissions for S3 Inventory and S3 analytics](#).

Inventory consistency

All of your objects might not appear in each inventory list. The inventory list provides eventual consistency for PUT requests (of both new objects and overwrites) and for DELETE requests. Each inventory list for a bucket is a snapshot of bucket items. These lists are eventually consistent (that is, a list might not include recently added or deleted objects).

To validate the state of an object before you take action on the object, we recommend that you perform a `HeadObject` REST API request to retrieve metadata for the object, or to check the object's properties in the Amazon S3 console. You can also check object metadata with the AWS CLI or the AWS SDKs. For more information, see [HeadObject](#) in the *Amazon Simple Storage Service API Reference*.

For more information about working with Amazon S3 Inventory, see the following topics.

Configuring Amazon S3 Inventory

Amazon S3 Inventory provides a flat file list of your objects and metadata, on a schedule that you define. You can use S3 Inventory as a scheduled alternative to the Amazon S3 synchronous `List` API operation. S3 Inventory provides comma-separated values (CSV), [Apache optimized row columnar \(ORC\)](#), or [Apache Parquet \(Parquet\)](#) output files that list your objects and their corresponding metadata.

You can configure S3 Inventory to create inventory lists on a daily or weekly basis for an S3 bucket or for objects that share a prefix (objects that have names that begin with the same string). For more information, see [Cataloging and analyzing your data with S3 Inventory](#).

This section describes how to configure an inventory, including details about the inventory source and destination buckets.

Topics

- [Overview](#)
- [Creating a destination bucket policy](#)
- [Granting Amazon S3 permission to use your customer managed key for encryption](#)
- [Configuring inventory by using the S3 console](#)
- [Using the REST API to work with S3 Inventory](#)

Overview

Amazon S3 Inventory helps you manage your storage by creating lists of the objects in an S3 bucket on a defined schedule. You can configure multiple inventory lists for a bucket. The inventory lists are published to CSV, ORC, or Parquet files in a destination bucket.

The easiest way to set up an inventory is by using the Amazon S3 console, but you can also use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. The console performs the first step of the following procedure for you: adding a bucket policy to the destination bucket.

To set up Amazon S3 Inventory for an S3 bucket

1. Add a bucket policy for the destination bucket.

You must create a bucket policy on the destination bucket that grants permissions to Amazon S3 to write objects to the bucket in the defined location. For an example policy, see [Grant permissions for S3 Inventory and S3 analytics](#).

2. Configure an inventory to list the objects in a source bucket and publish the list to a destination bucket.

When you configure an inventory list for a source bucket, you specify the destination bucket where you want the list to be stored, and whether you want to generate the list daily or weekly. You can also configure whether to list all object versions or only current versions and what object metadata to include.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key.

For more information about the optional metadata fields available in S3 Inventory, see [OptionalFields](#) in the *Amazon Simple Storage Service API Reference*. For more information about restricting access to certain optional metadata fields in an inventory configuration, see [Control S3 Inventory report configuration creation](#).

You can specify that the inventory list file be encrypted by using server-side encryption with an Amazon S3 managed key (SSE-S3) or an AWS Key Management Service (AWS KMS) customer managed key (SSE-KMS).

 **Note**

The AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

For more information about SSE-S3 and SSE-KMS, see [Protecting data with server-side encryption](#). If you plan to use SSE-KMS encryption, see Step 3.

- For information about how to use the console to configure an inventory list, see [Configuring inventory by using the S3 console](#).
- To use the Amazon S3 API to configure an inventory list, use the [PutBucketInventoryConfiguration](#) REST API operation or the equivalent from the AWS CLI or AWS SDKs.

3. To encrypt the inventory list file with SSE-KMS, grant Amazon S3 permission to use the AWS KMS key.

You can configure encryption for the inventory list file by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, or AWS SDKs. Whichever way you choose, you must grant Amazon S3 permission to use the customer managed key to encrypt the inventory file. You grant Amazon S3 permission by modifying the key policy for the customer managed key that you want to use

to encrypt the inventory file. For more information, see [Granting Amazon S3 permission to use your customer managed key for encryption](#).

The destination bucket that stores the inventory list file can be owned by a different AWS account than the account that owns the source bucket. If you use SSE-KMS encryption for the cross-account operations of Amazon S3 Inventory, we recommend that you use a fully qualified KMS key ARN when you configure S3 inventory. For more information, see [Using SSE-KMS encryption for cross-account operations](#) and [ServerSideEncryptionByDefault](#) in the *Amazon Simple Storage Service API Reference*.

Creating a destination bucket policy

If you create your inventory configuration through the Amazon S3 console, Amazon S3 automatically creates a bucket policy on the destination bucket that grants Amazon S3 write permission to the bucket. However, if you create your inventory configuration through the AWS CLI, AWS SDKs, or the Amazon S3 REST API, you must manually add a bucket policy on the destination bucket. The S3 Inventory destination bucket policy allows Amazon S3 to write data for the inventory reports to the bucket.

The following is the example bucket policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "InventoryExamplePolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "s3.amazonaws.com"  
            },  
            "Action": "s3:PutObject",  
            "Resource": [  
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"  
            ],  
            "Condition": {  
                "ArnLike": {  
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "source-account-id",  
                    "s3:x-amz-acl": "bucket-owner-full-control"  
                }  
            }  
        }  
    ]  
}
```

```
        }
    }
}
]
```

For more information, see [Grant permissions for S3 Inventory and S3 analytics](#).

If an error occurs when you try to create the bucket policy, you are given instructions on how to fix it. For example, if you choose a destination bucket in another AWS account and don't have permissions to read and write to the bucket policy, you see an error message.

In this case, the destination bucket owner must add the bucket policy to the destination bucket. If the policy is not added to the destination bucket, you won't get an inventory report because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, the correct account ID of the source bucket owner must be substituted in the policy.

 **Note**

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see [Why can't I generate an Amazon S3 Inventory Report?](#).

Granting Amazon S3 permission to use your customer managed key for encryption

To grant Amazon S3 permission to use your AWS Key Management Service (AWS KMS) customer managed key for server-side encryption, you must use a key policy. To update your key policy so that you can use your customer managed key, use the following procedure.

To grant Amazon S3 permissions to encrypt by using your customer managed key

1. Using the AWS account that owns the customer managed key, sign into the AWS Management Console.
2. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.

4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the customer managed key that you want to use to encrypt your inventory files.
6. In the **Key policy** section, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. On the **Edit key policy** page, add the following lines to the existing key policy. For *source-account-id* and *amzn-s3-demo-source-bucket*, supply the appropriate values for your use case.

```
{  
    "Sid": "Allow Amazon S3 use of the customer managed key",  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "s3.amazonaws.com"  
    },  
    "Action": [  
        "kms:GenerateDataKey"  
    ],  
    "Resource": "*",  
    "Condition":{  
        "StringEquals":{  
            "aws:SourceAccount":"source-account-id"  
        },  
        "ArnLike":{  
            "aws:SourceARN": "arn:aws:s3:::amzn-s3-demo-source-bucket"  
        }  
    }  
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following links in the *AWS Key Management Service Developer Guide*:

- [Managing keys](#)
- [Key policies in AWS KMS](#)

Note

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see [Why can't I generate an Amazon S3 Inventory Report?](#).

Configuring inventory by using the S3 console

Use these instructions to configure inventory by using the S3 console.

Note

It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to configure Amazon S3 Inventory for.
4. Choose the **Management** tab.
5. Under **Inventory configurations**, choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name.
7. For **Inventory scope**, do the following:
 - Enter an optional prefix.
 - Choose which object versions to include, either **Current versions only** or **Include all versions**.
8. Under **Report details**, choose the location of the AWS account that you want to save the reports to: **This account** or **A different account**.
9. Under **Destination**, choose the destination bucket where you want the inventory reports to be saved.

The destination bucket must be in the same AWS Region as the bucket for which you are setting up the inventory. The destination bucket can be in a different AWS account. When

specifying the destination bucket, you can also include an optional prefix to group your inventory reports together.

Under the **Destination** bucket field, you see the **Destination bucket permission** statement that is added to the destination bucket policy to allow Amazon S3 to place data in that bucket. For more information, see [Creating a destination bucket policy](#).

10. Under **Frequency**, choose how often the report will be generated, **Daily** or **Weekly**.
11. For **Output format**, choose one of the following formats for the report:
 - **CSV** – If you plan to use this inventory report with S3 Batch Operations or if you want to analyze this report in another tool, such as Microsoft Excel, choose **CSV**.
 - **Apache ORC**
 - **Apache Parquet**
12. Under **Status**, choose **Enable** or **Disable**.
13. To configure server-side encryption, under **Inventory report encryption**, follow these steps:
 - a. Under **Server-side encryption**, choose either **Do not specify an encryption key** or **Specify an encryption key** to encrypt data.
 - To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

 **Note**

If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must choose **Specify an encryption key**. Otherwise, copying objects to the destination will fail.

- To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.
- b. If you chose **Specify an encryption key**, under **Encryption type**, you must choose either **Amazon S3 managed key (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your

key. For more information about SSE-S3, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#). For more information about SSE-KMS, see [Using server-side encryption with AWS KMS keys \(SSE-KMS\)](#).

 **Note**

To encrypt the inventory list file with SSE-KMS, you must grant Amazon S3 permission to use the customer managed key. For instructions, see [Grant Amazon S3 Permission to Encrypt Using Your KMS Keys](#).

- c. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.

 **Note**

If the destination bucket that stores the inventory list file is owned by a different AWS account, make sure that you use a fully qualified KMS key ARN to specify your KMS key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose a symmetric encryption KMS key from the list of available keys. Make sure the KMS key is in the same Region as your bucket.

 **Note**

Both the AWS managed key (aws/s3) and your customer managed keys appear in the list. However, the AWS managed key (aws/s3) is not supported for SSE-KMS encryption with S3 Inventory.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

14. For **Additional metadata fields**, select one or more of the following to add to the inventory report:

- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Multipart upload** – Specifies that the object was uploaded as a multipart upload. For more information, see [Uploading and copying objects using multipart upload in Amazon S3](#).
- **Replication status** – The replication status of the object. For more information, see [Getting replication status information](#).
- **Encryption status** – The server-side encryption type that's used to encrypt the object. For more information, see [Protecting data with server-side encryption](#).
- **Bucket Key status** – Indicates whether a bucket-level key generated by AWS KMS applies to the object. For more information, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information about this field, see [Working with the Object ACL field](#). For more information about ACLs, see [Access control list \(ACL\) overview](#).
- **Object owner** – The owner of the object.
- **Storage class** – The storage class that's used for storing the object.
- **Intelligent-Tiering: Access tier** – Indicates the access tier (frequent or infrequent) of the object if it was stored in the S3 Intelligent-Tiering storage class. For more information, see [Storage class for automatically optimizing data with changing or unknown access patterns](#).
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag might or might not be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see [Object in the Amazon Simple Storage Service API Reference](#).
- **Checksum algorithm** – Indicates the algorithm that is used to create the checksum for the object. For more information, see [Using supported checksum algorithms](#).
- **All Object Lock configurations** – The Object Lock status of the object, including the following settings:
 - **Object Lock: Retention mode** – The level of protection applied to the object, either *Governance* or *Compliance*.

- **Object Lock: Retain until date** – The date until which the locked object cannot be deleted.
- **Object Lock: Legal hold status** – The legal hold status of the locked object.

For information about S3 Object Lock, see [How S3 Object Lock works](#).

For more information about the contents of an inventory report, see [Amazon S3 Inventory list](#).

For more information about restricting access to certain optional metadata fields in an inventory configuration, see [Control S3 Inventory report configuration creation](#).

15. Choose **Create**.

Using the REST API to work with S3 Inventory

The following are the REST operations that you can use to work with Amazon S3 Inventory.

- [DeleteBucketInventoryConfiguration](#)
- [GetBucketInventoryConfiguration](#)
- [ListBucketInventoryConfigurations](#)
- [PutBucketInventoryConfiguration](#)

Locating your inventory list

When an inventory list is published, the manifest files are published to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.json  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/  
manifest.checksum  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/hive/dt=YYYY-MM-DD-HH-MM/  
symlink.txt
```

- **destination-prefix** is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location within the destination bucket.

- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *config-ID* is added to prevent collisions with multiple inventory reports from the same source bucket that are sent to the same destination bucket. The *config-ID* comes from the inventory report configuration, and is the name for the report that is defined during setup.
- *YYYY-MM-DDTHH-MMZ* is the timestamp that consists of the start time and the date when the inventory report generation process begins scanning the bucket; for example, 2016-11-06T21-32Z.
- `manifest.json` is the manifest file.
- `manifest.checksum` is the MD5 hash of the content of the `manifest.json` file.
- `symlink.txt` is the Apache Hive-compatible manifest file.

The inventory lists are published daily or weekly to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name.csv.gz  
...  
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name-1.csv.gz
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location in the destination bucket.
- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *example-file-name.csv.gz* is one of the CSV inventory files. ORC inventory names end with the file name extension `.orc`, and Parquet inventory names end with the file name extension `.parquet`.

Inventory manifest

The manifest files `manifest.json` and `symlink.txt` describe where the inventory files are located. Whenever a new inventory list is delivered, it is accompanied by a new set of manifest files. These files might overwrite each other. In versioning-enabled buckets, Amazon S3 creates new versions of the manifest files.

Each manifest contained in the `manifest.json` file provides metadata and other basic information about an inventory. This information includes the following:

- The source bucket name
- The destination bucket name
- The version of the inventory
- The creation timestamp in the epoch date format that consists of the start time and the date when the inventory report generation process begins scanning the bucket
- The format and schema of the inventory files
- A list of the inventory files that are in the destination bucket

Whenever a `manifest.json` file is written, it is accompanied by a `manifest.checksum` file that is the MD5 hash of the content of the `manifest.json` file.

Example Inventory manifest in a `manifest.json` file

The following examples show an inventory manifest in a `manifest.json` file for CSV, ORC, and Parquet-formatted inventories.

CSV

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-inventory-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "CSV",  
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,  
    Size, LastModifiedDate, ETag, StorageClass, IsMultipartUploaded,  
    ReplicationStatus, EncryptionStatus, ObjectLockRetainUntilDate, ObjectLockMode,  
    ObjectLockLegalHoldStatus, IntelligentTieringAccessTier, BucketKeyStatus,  
    ChecksumAlgorithm, ObjectAccessControlList, ObjectOwner",  
    "files": [  
        {  
            "key": "Inventory/amzn-s3-demo-source-bucket/2016-11-06T21-32Z/  
            files/939c6d46-85a9-4ba8-87bd-9db705a579ce.csv.gz",  
        }  
    ]  
}
```

```
        "size": 2147483647,  
        "MD5checksum": "f11166069f1990abeb9c97ace9cdfabc"  
    }  
]  
}
```

ORC

The following is an example of a manifest in a `manifest.json` file for an ORC-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "ORC",  
    "fileSchema":  
        "struct<bucket:string,key:string,version_id:string,is_latest:boolean,is_delete_marker:boolean>  
    "files": [  
        {  
            "key": "inventory/amzn-s3-demo-source-bucket/data/  
d794c570-95bb-4271-9128-26023c8b4900.orc",  
            "size": 56291,  
            "MD5checksum": "5925f4e78e1695c2d020b9f6eexample"  
        }  
    ]  
}
```

Parquet

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted inventory.

```
{  
    "sourceBucket": "amzn-s3-demo-source-bucket",  
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",  
    "version": "2016-11-30",  
    "creationTimestamp" : "1514944800000",  
    "fileFormat": "Parquet",  
    "fileSchema": "message s3.inventory { required binary bucket (UTF8);  
required binary key (UTF8); optional binary version_id (UTF8); optional boolean  
is_latest; optional boolean is_delete_marker; optional int64 size; optional
```

```
int64 last_modified_date (TIMESTAMP_MILLIS); optional binary e_tag (UTF8);
optional binary storage_class (UTF8); optional boolean is_multipart_uploaded;
optional binary replication_status (UTF8); optional binary encryption_status
(UTF8); optional int64 object_lock_retain_until_date (TIMESTAMP_MILLIS); optional
binary object_lock_mode (UTF8); optional binary object_lock_legal_hold_status
(UTF8); optional binary intelligent_tiering_access_tier (UTF8); optional binary
bucket_key_status (UTF8); optional binary checksum_algorithm (UTF8); optional
binary object_access_control_list (UTF8); optional binary object_owner (UTF8);}",
"files": [
{
    "key": "inventory/amzn-s3-demo-source-bucket/data/
d754c470-85bb-4255-9218-47023c8b4910.parquet",
    "size": 56291,
    "MD5checksum": "5825f2e18e1695c2d030b9f6eexample"
}
]
```

The `symlink.txt` file is an Apache Hive-compatible manifest file that allows Hive to automatically discover inventory files and their associated data files. The Hive-compatible manifest works with the Hive-compatible services Athena and Amazon Redshift Spectrum. It also works with Hive-compatible applications, including [Presto](#), [Apache Hive](#), [Apache Spark](#), and many others.

 **Important**

The `symlink.txt` Apache Hive-compatible manifest file does not currently work with AWS Glue.

Reading the `symlink.txt` file with [Apache Hive](#) and [Apache Spark](#) is not supported for ORC and Parquet-formatted inventory files.

Setting up Amazon S3 Event Notifications for inventory completion

You can set up an Amazon S3 event notification to receive notice when the manifest checksum file is created, which indicates that an inventory list has been added to the destination bucket. The manifest is an up-to-date list of all the inventory lists at the destination location.

Amazon S3 can publish events to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see [Amazon S3 Event Notifications](#).

The following notification configuration defines that all `manifest.checksum` files newly added to the destination bucket are processed by the AWS Lambda `cloud-function-list-write`.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>1</Id>
    <Filter>
      <S3Key>
        <FilterRule>
          <Name>prefix</Name>
          <Value>destination-prefix/source-bucket</Value>
        </FilterRule>
        <FilterRule>
          <Name>suffix</Name>
          <Value>checksum</Value>
        </FilterRule>
      </S3Key>
    </Filter>
    <CloudFunction>arn:aws:lambda:us-west-2:22223334444:cloud-function-list-write</CloudFunction>
    <Event>s3:ObjectCreated:*</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

For more information, see [Using AWS Lambda with Amazon S3](#) in the *AWS Lambda Developer Guide*.

Querying Amazon S3 Inventory with Amazon Athena

You can query Amazon S3 Inventory files with standard SQL queries by using Amazon Athena in all Regions where Athena is available. To check for AWS Region availability, see the [AWS Region Table](#).

Athena can query Amazon S3 Inventory files in [Apache optimized row columnar \(ORC\)](#), [Apache Parquet](#), or comma-separated values (CSV) format. When you use Athena to query inventory files, we recommend that you use ORC-formatted or Parquet-formatted inventory files. The ORC and Parquet formats provide faster query performance and lower query costs. ORC and Parquet are self-describing, type-aware columnar file formats designed for [Apache Hadoop](#). The columnar format lets the reader read, decompress, and process only the columns that are required for the current query. The ORC and Parquet formats for Amazon S3 Inventory are available in all AWS Regions.

To use Athena to query Amazon S3 Inventory files

1. Create an Athena table. For information about creating a table, see [Creating Tables in Amazon Athena](#) in the *Amazon Athena User Guide*.
2. Create your query by using one of the following sample query templates, depending on whether you're querying an ORC-formatted, a Parquet-formatted, or a CSV-formatted inventory report.
 - When you're using Athena to query an ORC-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an ORC-formatted inventory report.

To use this sample query, do the following:

- Replace *your_table_name* with the name of the Athena table that you created.
- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

s3://amzn-s3-demo-bucket/config-ID/hive/

- Replace the *2022-01-01-00-00* date under *projection.dt.range* with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name(  
    bucket string,  
    key string,  
    version_id string,  
    is_latest boolean,  
    is_delete_marker boolean,  
    size bigint,  
    last_modified_date timestamp,  
    e_tag string,  
    storage_class string,  
    is_multipart_uploaded boolean,  
    replication_status string,  
    encryption_status string,
```

```
        object_lock_retain_until_date bigint,
        object_lock_mode string,
        object_lock_legal_hold_status string,
        intelligent_tiering_access_tier string,
        bucket_key_status string,
        checksum_algorithm string,
        object_access_control_list string,
        object_owner string
    ) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
    STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
    OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
    LOCATION 's3://source-bucket/config-ID/hive/
TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
);
```

- When you're using Athena to query a Parquet-formatted inventory report, use the sample query for an ORC-formatted report. However, use the following Parquet SerDe in place of the ORC SerDe in the ROW FORMAT SERDE statement.

```
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
```

- When you're using Athena to query a CSV-formatted inventory report, use the following sample query as a template.

The following sample query includes all the optional fields in an CSV-formatted inventory report.

To use this sample query, do the following:

- Replace *your_table_name* with the name of the Athena table that you created.
- Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.

- Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

s3://*amzn-s3-demo-bucket/config-ID/hive/*

- Replace the *2022-01-01-00-00* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see [Partitioning data in Athena](#).

```
CREATE EXTERNAL TABLE your_table_name(  
    bucket string,  
    key string,  
    version_id string,  
    is_latest boolean,  
    is_delete_marker boolean,  
    size string,  
    last_modified_date string,  
    e_tag string,  
    storage_class string,  
    is_multipart_uploaded boolean,  
    replication_status string,  
    encryption_status string,  
    object_lock_retain_until_date string,  
    object_lock_mode string,  
    object_lock_legal_hold_status string,  
    intelligent_tiering_access_tier string,  
    bucket_key_status string,  
    checksum_algorithm string,  
    object_access_control_list string,  
    object_owner string  
) PARTITIONED BY (  
    dt string  
)  
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.OpenCSVSerde'  
STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'  
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'  
LOCATION 's3://source-bucket/config-ID/hive/'  
TBLPROPERTIES (  
    "projection.enabled" = "true",  
    "projection.dt.type" = "date",  
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",  
    "projection.dt.range" = "2022-01-01-00-00,NOW",  
    "projection.dt.interval" = "1",
```

```
    "projection.dt.interval.unit" = "HOURS"
);
```

3. You can now run various queries on your inventory, as shown in the following examples. Replace each *user input placeholder* with your own information.

```
# Get a list of the latest inventory report dates available.
SELECT DISTINCT dt FROM your_table_name ORDER BY 1 DESC limit 10;

# Get the encryption status for a provided report date.
SELECT encryption_status, count(*) FROM your_table_name WHERE dt = 'YYYY-MM-DD-HH-MM' GROUP BY encryption_status;

# Get the encryption status for inventory report dates in the provided range.
SELECT dt, encryption_status, count(*) FROM your_table_name
WHERE dt > 'YYYY-MM-DD-HH-MM' AND dt < 'YYYY-MM-DD-HH-MM' GROUP BY dt,
encryption_status;
```

When you configure S3 Inventory to add the Object Access Control List (Object ACL) field to an inventory report, the report displays the value for the Object ACL field as a base64-encoded string. To get the decoded value in JSON for the Object ACL field, you can query this field by using Athena. See the following query examples. For more information about the Object ACL field, see [Working with the Object ACL field](#).

```
# Get the S3 keys that have Object ACL grants with public access.
WITH grants AS (
    SELECT key,
    CAST(
        json_extract(from_utf8(from_base64(object_access_control_list)),
        '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
    ) AS grants_array
    FROM your_table_name
)
SELECT key,
    grants_array,
    grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'uri') = 'http://acs.amazonaws.com/groups/global/AllUsers'
```

```
# Get the S3 keys that have Object ACL grantees in addition to the object owner.
```

```
WITH grants AS
  (SELECT key,
    from_utf8(from_base64(object_access_control_list)) AS
object_access_control_list,
    object_owner,
    CAST(json_extract(from_utf8(from_base64(object_access_control_list)),
      '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))) AS grants_array
  FROM your_table_name)
SELECT key,
  grant,
  objectowner
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE cardinality(grants_array) > 1 AND element_at(grant, 'canonicalId') != object_owner;
```

```
# Get the S3 keys with READ permission that is granted in the Object ACL.
WITH grants AS (
  SELECT key,
    CAST(
      json_extract(from_utf8(from_base64(object_access_control_list)),
        '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
      ) AS grants_array
  FROM your_table_name
)
SELECT key,
  grants_array,
  grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'permission') = 'READ';
```

```
# Get the S3 keys that have Object ACL grants to a specific canonical user ID.
WITH grants AS (
  SELECT key,
    CAST(
      json_extract(from_utf8(from_base64(object_access_control_list)),
        '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
      ) AS grants_array
  FROM your_table_name
)
SELECT key,
```

```
    grants_array,  
    grant  
FROM grants, UNNEST(grants_array) AS t(grant)  
WHERE element_at(grant, 'canonicalId') = 'user-canonical-id';
```

```
# Get the number of grantees on the Object ACL.  
SELECT key,  
       object_access_control_list,  
       json_array_length(json_extract(object_access_control_list,'$.grants')) AS  
       grants_count  
FROM your_table_name;
```

For more information about using Athena, see the [Amazon Athena User Guide](#).

Converting empty version ID strings in Amazon S3 Inventory reports to null strings

Note

The following procedure applies only to Amazon S3 Inventory reports that include all versions, and only if the "all versions" reports are used as manifests for S3 Batch Operations on buckets that have S3 Versioning enabled. You are not required to convert strings for S3 Inventory reports that specify the current version only.

You can use S3 Inventory reports as manifests for S3 Batch Operations. However, when S3 Versioning is enabled on a bucket, S3 Inventory reports that include all versions mark any null-versioned objects with empty strings in the version ID field. When an Inventory Report includes all object version IDs, Batch Operations recognizes null strings as version IDs, but not empty strings.

When an S3 Batch Operations job uses an "all versions" S3 Inventory report as a manifest, it fails all tasks on objects that have an empty string in the version ID field. To convert empty strings in the version ID field of the S3 Inventory report to null strings for Batch Operations, use the following procedure.

Update an Amazon S3 Inventory report for use with Batch Operations

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Navigate to your S3 Inventory report. The inventory report is located in the destination bucket that you specified while configuring your inventory report. For more information about locating inventory reports, see [Locating your inventory list](#).
 - a. Choose the destination bucket.
 - b. Choose the folder. The folder is named after the original source bucket.
 - c. Choose the folder named after the inventory configuration.
 - d. Select the check box next to the folder named **hive**. At the top of the page, choose **Copy S3 URI** to copy the S3 URI for the folder.
3. Open the Amazon Athena console at <https://console.aws.amazon.com/athena/>.
4. In the query editor, choose **Settings**, then choose **Manage**. On the **Manage settings** page, for **Location of query result**, choose an S3 bucket to store your query results in.
5. In the query editor, create an Athena table to hold the data in the inventory report using the following command. Replace **table_name** with a name of your choosing, and in the LOCATION clause, insert the S3 URI that you copied earlier. Then choose **Run** to run the query.

```
CREATE EXTERNAL TABLE table_name(bucket string, key string,  
version_id string) PARTITIONED BY (dt string)ROW FORMAT SERDE  
'org.apache.hadoop.hive.serde2.OpenCSVSerde' STORED AS INPUTFORMAT  
'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat' OUTPUTFORMAT  
'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat' LOCATION 'Copied S3 URI';
```

6. To clear the query editor, choose **Clear**. Then load the inventory report into the table using the following command. Replace **table_name** with the one that you chose in the prior step. Then choose **Run** to run the query.

```
MSCK REPAIR TABLE table_name;
```

7. To clear the query editor, choose **Clear**. Run the following SELECT query to retrieve all entries in the original inventory report and replace any empty version IDs with null strings. Replace **table_name** with the one that you chose earlier, and replace **YYYY-MM-DD-HH-MM** in the WHERE clause with the date of the inventory report that you want this tool to run on. Then choose **Run** to run the query.

```
SELECT bucket as Bucket, key as Key, CASE WHEN version_id = '' THEN 'null' ELSE version_id END as VersionId FROM table_name WHERE dt = 'YYYY-MM-DD-HH-MM';
```

8. Return to the Amazon S3 console (<https://console.aws.amazon.com/s3/>), and navigate to the S3 bucket that you chose for **Location of query result** earlier. Inside, there should be a series of folders ending with the date.

For example, you should see something like `s3://amzn-s3-demo-bucket/query-result-location/Unsaved/2021/10/07/`. You should see .csv files containing the results of the SELECT query that you ran.

Choose the CSV file with the latest modified date. Download this file to your local machine for the next step.

9. The generated CSV file contains a header row. To use this CSV file as input for an S3 Batch Operations job, you must remove the header row, because Batch Operations doesn't support header rows on CSV manifests.

To remove the header row, you can run one of the following commands on the file. Replace `file.csv` with the name of your CSV file.

For macOS and Linux machines, run the tail command in a Terminal window.

```
tail -n +2 file.csv > tmp.csv && mv tmp.csv file.csv
```

For Windows machines, run the following script in a Windows PowerShell window. Replace `File-location` with the path to your file, and `file.csv` with the file name.

```
$ins = New-Object System.IO.StreamReader File-location\file.csv
$outs = New-Object System.IO.StreamWriter File-location\temp.csv
try {
    $skip = 0
    while ( !$ins.EndOfStream ) {
        $line = $ins.ReadLine();
        if ( $skip -ne 0 ) {
            $outs.WriteLine($line);
        } else {
            $skip = 1
        }
    }
}
```

```
    } finally {
        $outs.Close();
        $ins.Close();
    }
Move-Item File-location\temp.csv File-location\file.csv -Force
```

10. After removing the header row from the CSV file, you are ready to use it as a manifest in an S3 Batch Operations job. Upload the CSV file to an S3 bucket or location of your choosing, and then create a Batch Operations job using the CSV file as the manifest.

For more information about creating a Batch Operations job, see [Creating an S3 Batch Operations job](#).

Working with the Object ACL field

An Amazon S3 Inventory report contains a list of the objects in the S3 source bucket and metadata for each object. The Object access control list (ACL) field is a metadata field that is available in Amazon S3 Inventory. Specifically, the Object ACL field contains the access control list (ACL) for each object. The ACL for an object defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information, see [Access control list \(ACL\) overview](#) and [Amazon S3 Inventory list](#).

The Object ACL field in Amazon S3 Inventory reports is defined in JSON format. The JSON data includes the following fields:

- **version** – The version of the Object ACL field format in the inventory reports. It's in date format yyyy-mm-dd.
- **status** – Possible values are AVAILABLE or UNAVAILABLE to indicate whether an Object ACL is available for an object. When the status for the Object ACL is UNAVAILABLE, the value of the Object Owner field in the inventory report is also UNAVAILABLE.
- **grants** – Grantee-permission pairs that list the permission status of each grantee that is granted by the Object ACL. The available values for a grantee are CanonicalUser and Group. For more information about grantees, see [Grantees in access control lists](#).

For a grantee with the Group type, a grantee-permission pair includes the following attributes:

- **uri** – A predefined Amazon S3 group.
- **permission** – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).

- type – The type `Group`, which denotes that the grantee is group.

For a grantee with the `CanonicalUser` type, a grantee-permission pair includes the following attributes:

- `canonicalId` – An obfuscated form of the AWS account ID. The canonical user ID for an AWS account is specific to that account. You can retrieve the canonical user ID. For more information see [Find the canonical user ID for your AWS account](#) in the *AWS Account Management Reference Guide*.

 **Note**

If a grantee in an ACL is the email address of an AWS account, S3 Inventory uses the `canonicalId` of that AWS account and the `CanonicalUser` type to specify this grantee. For more information, see [Grantees in access control lists](#).

- `permission` – The ACL permissions that are granted on the object. For more information, see [ACL permissions on an object](#).
- `type` – The type `CanonicalUser`, which denotes that the grantee is an AWS account.

The following example shows possible values for the Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {  
            "uri": "http://acs.amazonaws.com/groups/global/AllUsers",  
            "permission": "READ",  
            "type": "Group"  
        }, {  
            "canonicalId": "example-canonical-id",  
            "permission": "FULL_CONTROL",  
            "type": "CanonicalUser"  
        }]  
}
```

 **Note**

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.

For example, suppose that you have the following Object ACL field in JSON format:

```
{  
    "version": "2022-11-10",  
    "status": "AVAILABLE",  
    "grants": [  
        {"canonicalId": "example-canonical-user-ID",  
         "type": "CanonicalUser",  
         "permission": "READ"  
     ]  
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQU1MQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2FsSW
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see [Querying Amazon S3 Inventory with Amazon Athena](#).

Best practices design patterns: optimizing Amazon S3 performance

Your applications can easily achieve thousands of transactions per second in request performance when uploading and retrieving storage from Amazon S3. Amazon S3 automatically scales to high request rates. For example, your application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per partitioned Amazon S3 prefix. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by using parallelization. For example, if you create 10 prefixes in an Amazon S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second. Similarly, you can scale write operations by writing to multiple prefixes. The scaling, in the case of both read and write operations, happens gradually and is not instantaneous. While Amazon S3 is scaling to your new higher request rate, you may see some 503 (Slow Down) errors. These errors will dissipate when the scaling is complete. For more information about creating and using prefixes, see [Organizing objects using prefixes](#).

Some data lake applications on Amazon S3 scan millions or billions of objects for queries that run over petabytes of data. These data lake applications achieve single-instance transfer rates that maximize the network interface use for their [Amazon EC2](#) instance, which can be up to 100 Gb/s on a single instance. These applications then aggregate throughput across multiple instances to get multiple terabits per second.

Other applications are sensitive to latency, such as social media messaging applications. These applications can achieve consistent small object latencies (and first-byte-out latencies for larger objects) of roughly 100–200 milliseconds.

Other AWS services can also help accelerate performance for different application architectures. For example, if you want higher transfer rates over a single HTTP connection or single-digit millisecond latencies, use [Amazon CloudFront](#) or [Amazon ElastiCache](#) for caching with Amazon S3.

Additionally, if you want fast data transport over long distances between a client and an S3 bucket, use [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#). Transfer Acceleration uses the globally distributed edge locations in CloudFront to accelerate data transport over geographical distances. If your Amazon S3 workload uses server-side encryption with AWS KMS, see [AWS KMS Limits](#) in the AWS Key Management Service Developer Guide for information about the request rates supported for your use case.

The following topics describe best practice guidelines and design patterns for optimizing performance for applications that use Amazon S3. Refer to the [Performance guidelines for Amazon S3](#) and [Performance design patterns for Amazon S3](#) for the most current information about performance optimization for Amazon S3.

 **Note**

For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see [S3 Express One Zone](#) and [Working with directory buckets](#).

Topics

- [Performance guidelines for Amazon S3](#)
- [Performance design patterns for Amazon S3](#)

Performance guidelines for Amazon S3

When building applications that upload and retrieve objects from Amazon S3, follow our best practices guidelines to optimize performance. We also offer more detailed [Performance design patterns for Amazon S3](#).

To obtain the best performance for your application on Amazon S3, we recommend the following guidelines.

Topics

- [Measure performance](#)
- [Scale storage connections horizontally](#)
- [Use byte-range fetches](#)
- [Retry requests for latency-sensitive applications](#)
- [Combine Amazon S3 \(Storage\) and Amazon EC2 \(compute\) in the same AWS Region](#)
- [Use Amazon S3 Transfer Acceleration to minimize latency caused by distance](#)
- [Use the latest version of the AWS SDKs](#)

Measure performance

When optimizing performance, look at network throughput, CPU, and DRAM requirements. Depending on the mix of demands for these different resources, it might be worth evaluating different [Amazon EC2](#) instance types. For more information about instance types, see [Instance Types](#) in the *Amazon EC2 User Guide*.

It's also helpful to look at DNS lookup time, latency, and data transfer speed using HTTP analysis tools when measuring performance.

To understand the performance requirements and optimize the performance of your application, you can also monitor the 503 error responses that you receive. Monitoring certain performance metrics may incur additional expenses. For more information, see [Amazon S3 pricing](#).

Monitor the number of 503 (Slow Down) status error responses

To monitor the number of 503 status error responses that you get, you can use one of the following options:

- Use Amazon CloudWatch request metrics for Amazon S3. The CloudWatch request metrics include a metric for 5xx status responses. For more information about CloudWatch request metrics, see [Monitoring metrics with Amazon CloudWatch](#).
- Use the 503 (Service Unavailable) error count available in the advanced metrics section of Amazon S3 Storage Lens. For more information, see [Using S3 Storage Lens metrics to improve performance](#).
- Use Amazon S3 server access logging. With server access logging, you can filter and review all requests that receive 503 (Internal Error) responses. You can also use Amazon Athena to parse logs. For more information about server access logging, see [Logging requests with server access logging](#).

By monitoring the number of HTTP 503 status error code, you can often gain valuable insights into which prefixes, keys, or buckets are getting the most throttling requests.

Scale storage connections horizontally

Spreading requests across many connections is a common design pattern to horizontally scale performance. When you build high performance applications, think of Amazon S3 as a very large

distributed system, not as a single network endpoint like a traditional storage server. You can achieve the best performance by issuing multiple concurrent requests to Amazon S3. Spread these requests over separate connections to maximize the accessible bandwidth from Amazon S3. Amazon S3 doesn't have any limits for the number of connections made to your bucket.

Use byte-range fetches

Using the Range HTTP header in a [GET Object](#) request, you can fetch a byte-range from an object, transferring only the specified portion. You can use concurrent connections to Amazon S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. Fetching smaller ranges of a large object also allows your application to improve retry times when requests are interrupted. For more information, see [Downloading objects](#).

Typical sizes for byte-range requests are 8 MB or 16 MB. If objects are PUT using a multipart upload, it's a good practice to GET them in the same part sizes (or at least aligned to part boundaries) for best performance. GET requests can directly address individual parts; for example, GET ?partNumber=N.

Retry requests for latency-sensitive applications

Aggressive timeouts and retries help drive consistent latency. Given the large scale of Amazon S3, if the first request is slow, a retried request is likely to take a different path and quickly succeed. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region

Although S3 bucket names are globally unique, each bucket is stored in a Region that you select when you create the bucket. To learn more about bucket naming guidelines, see [Buckets overview](#) and [Bucket naming rules](#). To optimize performance, we recommend that you access the bucket from Amazon EC2 instances in the same AWS Region when possible. This helps reduce network latency and data transfer costs.

For more information about data transfer costs, see [Amazon S3 Pricing](#).

Use Amazon S3 Transfer Acceleration to minimize latency caused by distance

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) manages fast, easy, and secure transfers of files over long geographic distances between the client and an S3 bucket. Transfer Acceleration takes advantage of the globally distributed edge locations in [Amazon CloudFront](#). As the data arrives at an edge location, it is routed to Amazon S3 over an optimized network path. Transfer Acceleration is ideal for transferring gigabytes to terabytes of data regularly across continents. It's also useful for clients that upload to a centralized bucket from all over the world.

You can use the [Amazon S3 Transfer Acceleration Speed comparison tool](#) to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Amazon S3 Transfer Acceleration.

Use the latest version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs provide a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs include logic to automatically retry requests on HTTP 503 errors and are investing in code to respond and adapt to slow connections.

The SDKs also provide the [Transfer Manager](#), which automates horizontally scaling connections to achieve thousands of requests per second, using byte-range requests where appropriate. It's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

You can also optimize performance when you are using HTTP REST API requests. When using the REST API, you should follow the same best practices that are part of the SDKs. Allow for timeouts and retries on slow requests, and multiple connections to allow fetching of object data in parallel. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Performance design patterns for Amazon S3

When designing applications to upload and retrieve objects from Amazon S3, use our best practices design patterns for achieving the best performance for your application. We also offer

[Performance guidelines for Amazon S3](#) for you to consider when planning your application architecture.

To optimize performance, you can use the following design patterns.

Topics

- [Using caching for frequently accessed content](#)
- [Timeouts and retries for latency-sensitive applications](#)
- [Horizontal scaling and request parallelization for high throughput](#)
- [Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers](#)

Using caching for frequently accessed content

Many applications that store data in Amazon S3 serve a “working set” of data that is repeatedly requested by users. If a workload is sending repeated GET requests for a common set of objects, you can use a cache such as [Amazon CloudFront](#), [Amazon ElastiCache](#), or [AWS Elemental MediaStore](#) to optimize performance. Successful cache adoption can result in low latency and high data transfer rates. Applications that use caching also send fewer direct requests to Amazon S3, which can help reduce request costs.

Amazon CloudFront is a fast content delivery network (CDN) that transparently caches data from Amazon S3 in a large set of geographically distributed points of presence (PoPs). When objects might be accessed from multiple Regions, or over the internet, CloudFront allows data to be cached close to the users that are accessing the objects. This can result in high performance delivery of popular Amazon S3 content. For information about CloudFront, see the [Amazon CloudFront Developer Guide](#).

Amazon ElastiCache is a managed, in-memory cache. With ElastiCache, you can provision Amazon EC2 instances that cache objects in memory. This caching results in orders of magnitude reduction in GET latency and substantial increases in download throughput. To use ElastiCache, you modify application logic to both populate the cache with hot objects and check the cache for hot objects before requesting them from Amazon S3. For examples of using ElastiCache to improve Amazon S3 GET performance, see the blog post [Turbocharge Amazon S3 with Amazon ElastiCache for Redis](#).

AWS Elemental MediaStore is a caching and content distribution system specifically built for video workflows and media delivery from Amazon S3. MediaStore provides end-to-end storage APIs specifically for video, and is recommended for performance-sensitive video workloads. For information about MediaStore, see the [AWS Elemental MediaStore User Guide](#).

Timeouts and retries for latency-sensitive applications

There are certain situations where an application receives a response from Amazon S3 indicating that a retry is necessary. Amazon S3 maps bucket and object names to the object data associated with them. If an application generates high request rates (typically sustained rates of over 5,000 requests per second to a small number of objects), it might receive HTTP 503 *slowdown* responses. If these errors occur, each AWS SDK implements automatic retry logic using exponential backoff. If you are not using an AWS SDK, you should implement retry logic when receiving the HTTP 503 error. For information about back-off techniques, see [Retry behavior](#) in the *AWS SDKs and Tools Reference Guide*.

Amazon S3 automatically scales in response to sustained new request rates, dynamically optimizing performance. While Amazon S3 is internally optimizing for a new request rate, you will receive HTTP 503 request responses temporarily until the optimization completes. After Amazon S3 internally optimizes performance for the new request rate, all requests are generally served without retries.

For latency-sensitive applications, Amazon S3 advises tracking and aggressively retrying slower operations. When you retry a request, we recommend using a new connection to Amazon S3 and performing a fresh DNS lookup.

When you make large variably sized requests (for example, more than 128 MB), we advise tracking the throughput being achieved and retrying the slowest 5 percent of the requests. When you make smaller requests (for example, less than 512 KB), where median latencies are often in the tens of milliseconds range, a good guideline is to retry a GET or PUT operation after 2 seconds. If additional retries are needed, the best practice is to back off. For example, we recommend issuing one retry after 2 seconds and a second retry after an additional 4 seconds.

If your application makes fixed-size requests to Amazon S3, you should expect more consistent response times for each of these requests. In this case, a simple strategy is to identify the slowest 1 percent of requests and to retry them. Even a single retry is frequently effective at reducing latency.

If you are using AWS Key Management Service (AWS KMS) for server-side encryption, see [Quotas](#) in the *AWS Key Management Service Developer Guide* for information about the request rates that are supported for your use case.

Horizontal scaling and request parallelization for high throughput

Amazon S3 is a very large distributed system. To help you take advantage of its scale, we encourage you to horizontally scale parallel requests to the Amazon S3 service endpoints. In addition to distributing the requests within Amazon S3, this type of scaling approach helps distribute the load over multiple paths through the network.

For high-throughput transfers, Amazon S3 advises using applications that use multiple connections to GET or PUT data in parallel. For example, this is supported by [Amazon S3 Transfer Manager](#) in the AWS Java SDK, and most of the other AWS SDKs provide similar constructs. For some applications, you can achieve parallel connections by launching multiple requests concurrently in different application threads, or in different application instances. The best approach to take depends on your application and the structure of the objects that you are accessing.

You can use the AWS SDKs to issue GET and PUT requests directly rather than employing the management of transfers in the AWS SDK. This approach lets you tune your workload more directly, while still benefiting from the SDK's support for retries and its handling of any HTTP 503 responses that might occur. As a general rule, when you download large objects within a Region from Amazon S3 to [Amazon EC2](#), we suggest making concurrent requests for byte ranges of an object at the granularity of 8–16 MB. Make one concurrent request for each 85–90 MB/s of desired network throughput. To saturate a 10 Gb/s network interface card (NIC), you might use about 15 concurrent requests over separate connections. You can scale up the concurrent requests over more connections to saturate faster NICs, such as 25 Gb/s or 100 Gb/s NICs.

Measuring performance is important when you tune the number of requests to issue concurrently. We recommend starting with a single request at a time. Measure the network bandwidth being achieved and the use of other resources that your application uses in processing the data. You can then identify the bottleneck resource (that is, the resource with the highest usage), and hence the number of requests that are likely to be useful. For example, if processing one request at a time leads to a CPU usage of 25 percent, it suggests that up to four concurrent requests can be accommodated. Measurement is essential, and it is worth confirming resource use as the request rate is increased.

If your application issues requests directly to Amazon S3 using the REST API, we recommend using a pool of HTTP connections and re-using each connection for a series of requests. Avoiding per-request connection setup removes the need to perform TCP slow-start and Secure Sockets Layer (SSL) handshakes on each request. For information about using the REST API, see the [Amazon Simple Storage Service API Reference](#).

Finally, it's worth paying attention to DNS and double-checking that requests are being spread over a wide pool of Amazon S3 IP addresses. DNS queries for Amazon S3 cycle through a large list of IP endpoints. But caching resolvers or application code that reuses a single IP address do not benefit from address diversity and the load balancing that follows from it. Network utility tools such as the netstat command line tool can show the IP addresses being used for communication with Amazon S3, and we provide guidelines for DNS configurations to use. For more information about these guidelines, see [Making requests](#) in the *Amazon S3 API Reference*.

Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers

[Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#) is effective at minimizing or eliminating the latency caused by geographic distance between globally dispersed clients and a regional application using Amazon S3. Transfer Acceleration uses the globally distributed edge locations in CloudFront for data transport. The AWS edge network has points of presence in more than 50 locations. Today, it is used to distribute content through CloudFront and to provide rapid responses to DNS queries made to [Amazon Route 53](#).

The edge network also helps to accelerate data transfers into and out of Amazon S3. It is ideal for applications that transfer data across or between continents, have a fast internet connection, use large objects, or have a lot of content to upload. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path. In general, the farther away you are from an Amazon S3 Region, the higher the speed improvement you can expect from using Transfer Acceleration.

You can set up Transfer Acceleration on new or existing buckets. You can use a separate Amazon S3 Transfer Acceleration endpoint to use the AWS edge locations. The best way to test whether Transfer Acceleration helps client request performance is to use the [Amazon S3 Transfer Acceleration Speed Comparison tool](#). Network configurations and conditions vary from time to time and from location to location. So you are charged only for transfers where Amazon S3 Transfer Acceleration can potentially improve your upload performance. For information about using Transfer Acceleration with different AWS SDKs, see [Enabling and using S3 Transfer Acceleration](#).

Hosting a static website using Amazon S3

You can use Amazon S3 to host a static website. On a *static* website, individual webpages include static content. They might also contain client-side scripts.

Note

We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see [Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket](#) and [Deploying a static website from S3 using the Amplify console in the AWS Amplify Console User Guide](#).

For more information about hosting a static website on Amazon S3, including instructions and step-by-step walkthroughs, see the following topics.

Topics

- [Website endpoints](#)
- [Enabling website hosting](#)
- [Configuring an index document](#)
- [Configuring a custom error document](#)
- [Setting permissions for website access](#)
- [\(Optional\) Logging web traffic](#)
- [\(Optional\) Configuring a webpage redirect](#)
- [Using cross-origin resource sharing \(CORS\)](#)
- [Static website tutorials](#)

Website endpoints

When you configure your bucket as a static website, the website is available at the AWS Region-specific website endpoint of the bucket. Website endpoints are different from the endpoints where you send REST API requests. For more information about the differences between the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

Depending on your Region, your Amazon S3 website endpoint follows one of these two formats.

- **s3-website dash (-) Region** - `http://bucket-name.s3-website-Region.amazonaws.com`
- **s3-website dot (.) Region** - `http://bucket-name.s3-website.Region.amazonaws.com`

These URLs return the default index document that you configure for the website. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website Endpoints](#).

Note

To augment the security of your Amazon S3 static websites, the Amazon S3 website endpoint domains (for example, `s3-website-us-east-1.amazonaws.com` or `s3-website.ap-south-1.amazonaws.com`) are registered in the [Public Suffix List \(PSL\)](#). For further security, we recommend that you use cookies with a `_Host-` prefix if you ever need to set sensitive cookies in the domain name for your Amazon S3 static websites. This practice will help to defend your domain against cross-site request forgery attempts (CSRF). For more information see the [Set-Cookie](#) page in the Mozilla Developer Network.

If you want your website to be public, you must make all your content publicly readable for your customers to be able to access it at the website endpoint. For more information, see [Setting permissions for website access](#).

Important

- Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can do one of the following:
 - (Recommended) Use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your

websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see [Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket](#) and [Deploying a static website from S3 using the Amplify console](#) in the *AWS Amplify Console User Guide*.

- Use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see [How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket?](#) To use HTTPS with a custom domain, see [Configuring a static website using a custom domain registered with Route 53](#).
- Requester Pays buckets do not allow access through a website endpoint. Any request to such a bucket receives a 403 Access Denied response. For more information, see [Using Requester Pays buckets for storage transfers and usage](#).

Topics

- [Website endpoint examples](#)
- [Adding a DNS CNAME](#)
- [Using a custom domain with Route 53](#)
- [Key differences between a website endpoint and a REST API endpoint](#)

Website endpoint examples

The following examples show how you can access an Amazon S3 bucket that is configured as a static website.

Example — Requesting an object at the root level

To request a specific object that is stored at the root level in the bucket, use the following URL structure.

`http://bucket-name.s3-website.Region.amazonaws.com/object-name`

For example, the following URL requests the photo.jpg object that is stored at the root level in the bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/photo.jpg
```

Example — Requesting an object in a prefix

To request an object that is stored in a folder in your bucket, use this URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/folder-name/object-name
```

The following URL requests the docs/doc1.html object in your bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/docs/doc1.html
```

Adding a DNS CNAME

If you have a registered domain, you can add a DNS CNAME entry to point to the Amazon S3 website endpoint. For example, if you registered the domain www.example-bucket.com, you could create a bucket www.example-bucket.com, and add a DNS CNAME record that points to www.example-bucket.com.s3-website.*Region*.amazonaws.com. All requests to http://www.example-bucket.com are routed to www.example-bucket.com.s3-website.*Region*.amazonaws.com.

For more information, see [Customizing Amazon S3 URLs with CNAME records](#).

Using a custom domain with Route 53

Instead of accessing the website using an Amazon S3 website endpoint, you can use your own domain registered with Amazon Route 53 to serve your content—for example, example.com. You can use Amazon S3 with Route 53 to host a website at the root domain. For example, if you have the root domain example.com and you host your website on Amazon S3, your website visitors can access the site from their browser by entering either http://www.example.com or http://example.com.

For an example walkthrough, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Key differences between a website endpoint and a REST API endpoint

An Amazon S3 website endpoint is optimized for access from a web browser. The following table summarizes the key differences between a REST API endpoint and a website endpoint.

Key difference	REST API endpoint	Website endpoint
Access control	Supports both public and private content	Supports only publicly readable content
Error message handling	Returns an XML-formatted error response	Returns an HTML document
Redirection support	Not applicable	Supports both object-level and bucket-level redirects
Requests supported	Supports all bucket and object operations	Supports only GET and HEAD requests on objects
Responses to GET and HEAD requests at the root of a bucket	Returns a list of the object keys in the bucket	Returns the index document that is specified in the website configuration
Secure Sockets Layer (SSL) support	Supports SSL connections	Does not support SSL connections

For a complete list of Amazon S3 endpoints, see [Amazon S3 endpoints and quotas](#) in the *AWS General Reference*.

Enabling website hosting

When you configure a bucket as a static website, you must enable static website hosting, configure an index document, and set permissions.

You can enable static website hosting using the Amazon S3 console, REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

To configure your website with a custom domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Using the S3 console

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Using the REST API

For more information about sending REST requests directly to enable static website hosting, see the following sections in the Amazon Simple Storage Service API Reference:

- [PUT Bucket website](#)
- [GET Bucket website](#)
- [DELETE Bucket website](#)

Using the AWS SDKs

To host a static website on Amazon S3, you configure an Amazon S3 bucket for website hosting and then upload your website content to the bucket. You can also use the AWS SDKs to create, update, and delete the website configuration programmatically. The SDKs provide wrapper classes around the Amazon S3 REST API. If your application requires it, you can send REST API requests directly from your application.

.NET

The following example shows how to use the AWS SDK for .NET to manage website configuration for a bucket. To add a website configuration to a bucket, you provide a bucket name and a website configuration. The website configuration must include an index document and can contain an optional error document. These documents must be stored in the bucket. For more information, see [PUT Bucket website](#). For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

The following C# code example adds a website configuration to the specified bucket. The configuration specifies both the index document and the error document names. For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET in the AWS SDK for .NET Developer Guide](#).

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class WebsiteConfigTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string indexDocumentSuffix = "*** index object key ***"; // For example, index.html.
        private const string errorDocument = "*** error object key ***"; // For example, error.html.
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            AddWebsiteConfigurationAsync(bucketName, indexDocumentSuffix,
errorDocument).Wait();
        }

        static async Task AddWebsiteConfigurationAsync(string bucketName,
                                                string indexDocumentSuffix,
                                                string errorDocument)
        {
            try
            {
                // 1. Put the website configuration.
                PutBucketWebsiteRequest putRequest = new PutBucketWebsiteRequest()
                {
                    BucketName = bucketName,
                    WebsiteConfiguration = new WebsiteConfiguration()
                    {

```

```
        IndexDocumentSuffix = indexDocumentSuffix,
        ErrorDocument = errorDocument
    }
};

PutBucketWebsiteResponse response = await
client.PutBucketWebsiteAsync(putRequest);

        // 2. Get the website configuration.
GetBucketWebsiteRequest getRequest = new GetBucketWebsiteRequest()
{
    BucketName = bucketName
};
GetBucketWebsiteResponse getResponse = await
client.GetBucketWebsiteAsync(getRequest);
    Console.WriteLine("Index document: {0}",
getResponse.WebsiteConfiguration.IndexDocumentSuffix);
    Console.WriteLine("Error document: {0}",
getResponse.WebsiteConfiguration.ErrorDocument);
}
catch (AmazonS3Exception e)
{
    Console.WriteLine("Error encountered on server. Message:'{0}' when
writing an object", e.Message);
}
catch (Exception e)
{
    Console.WriteLine("Unknown encountered on server. Message:'{0}' when
writing an object", e.Message);
}
}
}
}
```

PHP

The following PHP example adds a website configuration to the specified bucket. The `create_website_config` method explicitly provides the index document and error document names. The example also retrieves the website configuration and prints the response. For more information about the Amazon S3 website feature, see [Hosting a static website using Amazon S3](#).

For more information about the AWS SDK for Ruby API, go to [AWS SDK for Ruby - Version 2](#).

```
require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Add the website configuration.
$s3->putBucketWebsite([
    'Bucket'              => $bucket,
    'WebsiteConfiguration' => [
        'IndexDocument' => ['Suffix' => 'index.html'],
        'ErrorDocument'  => ['Key'   => 'error.html']
    ]
]);

// Retrieve the website configuration.
$result = $s3->getBucketWebsite([
    'Bucket' => $bucket
]);
echo $result->getPath('IndexDocument/Suffix');

// Delete the website configuration.
$s3->deleteBucketWebsite([
    'Bucket' => $bucket
]);
```

Using the AWS CLI

For more information about using the AWS CLI to configure an S3 bucket as a static website, see [website](#) in the *AWS CLI Command Reference*.

Next, you must configure your index document and set permissions. For information, see [Configuring an index document](#) and [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring an index document

When you enable website hosting, you must also configure and upload an index document. An *index document* is a webpage that Amazon S3 returns when a request is made to the root of a website or any subfolder. For example, if a user enters `http://www.example.com` in the browser, the user is not requesting any specific page. In that case, Amazon S3 serves up the index document, which is sometimes referred to as the *default page*.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for your bucket, you upload an HTML file with the index document name to your bucket.

The trailing slash at the root-level URL is optional. For example, if you configure your website with `index.html` as the index document, either of the following URLs returns `index.html`.

```
http://example-bucket.s3-website.Region.amazonaws.com/  
http://example-bucket.s3-website.Region.amazonaws.com
```

For more information about Amazon S3 website endpoints, see [Website endpoints](#).

Index document and folders

In Amazon S3, a bucket is a flat container of objects. It does not provide any hierarchical organization as the file system on your computer does. However, you can create a logical hierarchy by using object key names that imply a folder structure.

For example, consider a bucket with three objects that have the following key names. Although these are stored with no physical hierarchical organization, you can infer the following logical folder structure from the key names:

- `sample1.jpg` — Object is at the root of the bucket.
- `photos/2006/Jan/sample2.jpg` — Object is in the `photos/2006/Jan` subfolder.
- `photos/2006/Feb/sample3.jpg` — Object is in the `photos/2006/Feb` subfolder.

In the Amazon S3 console, you can also create a folder in a bucket. For example, you can create a folder named `photos`. You can upload objects to the bucket or to the `photos` folder within the bucket. If you add the object `sample.jpg` to the bucket, the key name is `sample.jpg`. If you upload the object to the `photos` folder, the object key name is `photos/sample.jpg`.

If you create a folder structure in your bucket, you must have an index document at each level. In each folder, the index document must have the same name, for example, `index.html`. When a user specifies a URL that resembles a folder lookup, the presence or absence of a trailing slash determines the behavior of the website. For example, the following URL, with a trailing slash, returns the `photos/index.html` index document.

```
http://bucket-name.s3-website.Region.amazonaws.com/photos/
```

However, if you exclude the trailing slash from the preceding URL, Amazon S3 first looks for an object `photos` in the bucket. If the `photos` object is not found, it searches for an index document, `photos/index.html`. If that document is found, Amazon S3 returns a 302 Found message and points to the `photos/` key. For subsequent requests to `photos/`, Amazon S3 returns `photos/index.html`. If the index document is not found, Amazon S3 returns an error.

Configure an index document

To configure an index document using the S3 console, use the following procedure. You can also configure an index document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

Note

In a versioning-enabled bucket, you may upload multiple copies of the `index.html` but only the newest version will be resolved to. For more information about using S3 Versioning see, [Retaining multiple versions of objects with S3 Versioning](#).

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
```

```
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

- Drag and drop the index file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Next, you must set permissions for website access. For information, see [Setting permissions for website access](#).

You can also optionally configure an [error document](#), [web traffic logging](#), or a [redirect](#).

Configuring a custom error document

After you configure your bucket as a static website, when an error occurs, Amazon S3 returns an HTML error document. You can optionally configure your bucket with a custom error document so that Amazon S3 returns that document when an error occurs.

Note

Some browsers display their own error message when an error occurs, ignoring the error document that Amazon S3 returns. For example, when an HTTP 404 Not Found error occurs, Google Chrome might ignore the error document that Amazon S3 returns and display its own error.

Topics

- [Amazon S3 HTTP response codes](#)
- [Configuring a custom error document](#)

Amazon S3 HTTP response codes

The following table lists the subset of HTTP response codes that Amazon S3 returns when an error occurs.

HTTP error code	Description
301 Moved Permanently	When a user sends a request directly to the Amazon S3 website endpoint (<code>http://s3-website. <i>Region</i>.amazonaws.com/</code>), Amazon S3 returns a 301 Moved Permanently response and redirects those requests to <code>https://aws.amazon.com/s3/</code> .
302 Found	When Amazon S3 receives a request for a key x, <code>http://<i>bucket-name</i>.s3-website. <i>Region</i>.amazonaws.com/x</code> , without a trailing slash, it first looks for the object with the key name x. If the object is not found, Amazon S3 determines that the request is for subfolder x and redirects the request by adding a slash at the end, and returns 302 Found .

HTTP error code	Description
304 Not Modified	Amazon S3 uses request headers <code>If-Modified-Since</code> , <code>If-Unmodified-Since</code> , <code>If-Match</code> and/or <code>If-None-Match</code> to determine whether the requested object is same as the cached copy held by the client. If the object is the same, the website endpoint returns a 304 Not Modified response.
400 Malformed Request	The website endpoint responds with a 400 Malformed Request when a user attempts to access a bucket through the incorrect regional endpoint.
403 Forbidden	The website endpoint responds with a 403 Forbidden when a user request translates to an object that is not publicly readable. The object owner must make the object publicly readable using a bucket policy or an ACL.

HTTP error code	Description
404 Not Found	<p>The website endpoint responds with 404 Not Found for the following reasons:</p> <ul style="list-style-type: none">• Amazon S3 determines that the URL of the website refers to an object key that does not exist.• Amazon S3 infers that the request is for an index document that does not exist.• A bucket specified in the URL does not exist.• A bucket specified in the URL exists, but isn't configured as a website. <p>You can create a custom document that is returned for 404 Not Found. Make sure that the document is uploaded to the bucket configured as a website, and that the website hosting configuration is set to use the document.</p> <p>For information on how Amazon S3 interprets the URL as a request for an object or an index document, see Configuring an index document.</p>
500 Service Error	The website endpoint responds with a 500 Service Error when an internal server error occurs.
503 Service Unavailable	The website endpoint responds with a 503 Service Unavailable when Amazon S3 determines that you need to reduce your request rate.

For each of these errors, Amazon S3 returns a predefined HTML message. The following is an example HTML message that is returned for a **403 Forbidden** response.

403 Forbidden

- Code: AccessDenied
- Message: Access Denied
- RequestId: 873CA367A51F7EC7
- HostId: DdQezl9vkuw5luD5HKsFaTDm9KH4PZzCPRkW3igimILbTu1DiYlvXjgyd7pVxq32

An Error Occurred While Attempting to Retrieve a Custom Error Document

- Code: AccessDenied
- Message: Access Denied

Configuring a custom error document

When you configure your bucket as a static website, you can provide a custom error document that contains a user-friendly error message and additional help. Amazon S3 returns your custom error document for only the HTTP 4XX class of error codes.

To configure a custom error document using the S3 console, follow the steps below. You can also configure an error document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation. For more information, see the following:

- [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*
- [AWS::S3::Bucket WebsiteConfiguration](#) in the *AWS CloudFormation User Guide*
- [put-bucket-website](#) in the *AWS CLI Command Reference*

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **404.html**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error**

document name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Setting permissions for website access

When you configure a bucket as a static website, if you want your website to be public, you can grant public read access. To make your bucket publicly readable, you must disable block public access settings for the bucket and write a bucket policy that grants public read access. If your bucket contains objects that are not owned by the bucket owner, you might also need to add an object access control list (ACL) that grants everyone read access.

If you don't want to disable block public access settings for your bucket but you still want your website to be public, you can create a Amazon CloudFront distribution to serve your static website. For more information, see [Speeding up your website with Amazon CloudFront](#) or [Use an Amazon CloudFront distribution to serve a static website in the Amazon Route 53 Developer Guide](#).

Note

On the website endpoint, if a user requests an object that doesn't exist, Amazon S3 returns HTTP response code `404 (Not Found)`. If the object exists but you haven't granted

read permission on it, the website endpoint returns HTTP response code 403 (Access Denied). The user can use the response code to infer whether a specific object exists. If you don't want this behavior, you should not enable website support for your bucket.

Topics

- [Step 1: Edit S3 Block Public Access settings](#)
- [Step 2: Add a bucket policy](#)
- [Object access control lists](#)

Step 1: Edit S3 Block Public Access settings

If you want to configure an existing bucket as a static website that has public access, you must edit Block Public Access settings for that bucket. You might also have to edit your account-level Block Public Access settings. Amazon S3 applies the most restrictive combination of the bucket-level and account-level block public access settings.

For example, if you allow public access for a bucket but block all public access at the account level, Amazon S3 will continue to block public access to the bucket. In this scenario, you would have to edit your bucket-level and account-level Block Public Access settings. For more information, see [Blocking public access to your Amazon S3 storage](#).

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.

3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#) 

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 2: Add a bucket policy

To make the objects in your bucket publicly readable, you must write a bucket policy that grants everyone `s3:GetObject` permission.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Object access control lists

You can use a bucket policy to grant public read permission to your objects. However, the bucket policy applies only to objects that are owned by the bucket owner. If your bucket contains objects that aren't owned by the bucket owner, the bucket owner should use the object access control list (ACL) to grant public READ permission on those objects.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Important

If your bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To make an object publicly readable using an ACL, grant READ permission to the AllUsers group, as shown in the following grant element. Add this grant element to the object ACL. For information about managing ACLs, see [Access control list \(ACL\) overview](#).

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
  </Grantee>
  <Permission>READ</Permission>
</Grant>
```

(Optional) Logging web traffic

You can optionally enable Amazon S3 server access logging for a bucket that is configured as a static website. Server access logging provides detailed records for the requests that are made to your bucket. For more information, see [Logging requests with server access logging](#). If you plan to use Amazon CloudFront to [speed up your website](#), you can also use CloudFront logging. For more information, see [Configuring and Using Access Logs](#) in the *Amazon CloudFront Developer Guide*.

To enable server access logging for your static website bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the same Region where you created the bucket that is configured as a static website, create a general purpose bucket for logging, for example logs.example.com.
3. Create a folder for the server access logging log files (for example, logs).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, cdn).

For more information, see [Speeding up your website with Amazon CloudFront](#).

5. In the **Buckets** list, choose your bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
 - Browse to the folder and bucket location:

1. Choose **Browse S3**.
 2. Choose the bucket name, and then choose the logs folder.
 3. Choose **Choose path**.
- Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.
10. Choose **Save changes**.

In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

(Optional) Configuring a webpage redirect

If your Amazon S3 bucket is configured for static website hosting, you can configure redirects for your bucket or the objects in it. You have the following options for configuring redirects.

Topics

- [Redirect requests for your bucket's website endpoint to another bucket or domain](#)
- [Configure redirection rules to use advanced conditional redirects](#)
- [Redirect requests for an object](#)

Redirect requests for your bucket's website endpoint to another bucket or domain

You can redirect all requests to a website endpoint for a bucket to another bucket or domain. If you redirect all requests, any request made to the website endpoint is redirected to the specified bucket or domain.

For example, if your root domain is `example.com`, and you want to serve requests for both `http://example.com` and `http://www.example.com`, you must create two buckets named `example.com` and `www.example.com`. Then, maintain the content in the `example.com` bucket, and configure the other `www.example.com` bucket to redirect all requests to the `example.com` bucket. For more information, see [Configuring a Static Website Using a Custom Domain Name](#).

To redirect requests for a bucket website endpoint

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Under **Buckets**, choose the name of the bucket that you want to redirect requests from (for example, `www.example.com`).
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Redirect requests for an object**.
6. In the **Host name** box, enter the website endpoint for your bucket or your custom domain.

For example, if you are redirecting to a root domain address, you would enter `example.com`.

7. For **Protocol**, choose the protocol for the redirected requests (`none`, `http`, or `https`).
If you do not specify a protocol, the default option is `none`.
8. Choose **Save changes**.

Configure redirection rules to use advanced conditional redirects

Using advanced redirection rules, you can route requests conditionally according to specific object key names, prefixes in the request, or response codes. For example, suppose that you delete or rename an object in your bucket. You can add a routing rule that redirects the request to another object. If you want to make a folder unavailable, you can add a routing rule to redirect the request to another webpage. You can also add a routing rule to handle error conditions by routing requests that return the error to another domain when the error is processed.

When enabling static website hosting for your bucket, you can optionally specify advanced redirection rules. Amazon S3 has a limitation of 50 routing rules per website configuration. If you require more than 50 routing rules, you can use object redirect. For more information, see [Using the S3 console](#).

For more information about configuring routing rules using the REST API, see [PutBucketWebsite](#) in the *Amazon Simple Storage Service API Reference*.

Important

To create redirection rules in the new Amazon S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

To configure redirection rules for a static website

To add redirection rules for a bucket that already has static website hosting enabled, follow these steps.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of a bucket that you have configured as a static website.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. In **Redirection rules** box, enter your redirection rules in JSON.

In the S3 console you describe the rules using JSON. For JSON examples, see [Redirection rules examples](#). Amazon S3 has a limitation of 50 routing rules per website configuration.

7. Choose **Save changes**.

Routing rule elements

The following is general syntax for defining the routing rules in a website configuration in JSON and XML. To configure redirection rules in the new S3 console, you must use JSON. For JSON examples, see [Redirection rules examples](#).

JSON

```
[  
 {  
   "Condition": {  
     "HttpErrorCodeReturnedEquals": "string",  
     "KeyPrefixEquals": "string"  
   },  
   "Redirect": {  
     "HostName": "string",  
     "HttpRedirectCode": "string",  
     "Protocol": "http"|"https",  
     "ReplaceKeyPrefixWith": "string",  
     "ReplaceKeyWith": "string"  
   }  
 }  
 ]
```

Note: Redirect must each have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.

XML

```
<RoutingRules> =
<RoutingRules>
    <RoutingRule>...</RoutingRule>
    [<RoutingRule>...</RoutingRule>
     ...
    ]
</RoutingRules>

<RoutingRule> =
<RoutingRule>
    [ <Condition>...</Condition> ]
    <Redirect>...</Redirect>
</RoutingRule>

<Condition> =
<Condition>
    [ <KeyPrefixEquals>...</KeyPrefixEquals> ]
    [ <HttpErrorCodeReturnedEquals>...</HttpErrorCodeReturnedEquals> ]
</Condition>
Note: <Condition> must have at least one child element.

<Redirect> =
<Redirect>
    [ <HostName>...</HostName> ]
    [ <Protocol>...</Protocol> ]
    [ <ReplaceKeyPrefixWith>...</ReplaceKeyPrefixWith> ]
    [ <ReplaceKeyWith>...</ReplaceKeyWith> ]
    [ <HttpRedirectCode>...</HttpRedirectCode> ]
</Redirect>

Note: <Redirect> must have at least one child element. You can have either ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

The following table describes the elements in the routing rule.

Name	Description
RoutingRules	Container for a collection of <code>RoutingRule</code> elements.
RoutingRule	<p>A rule that identifies a condition and the redirect that is applied when the condition is met.</p> <p>Condition:</p> <ul style="list-style-type: none">• A <code>RoutingRules</code> container must contain at least one routing rule.
Condition	Container for describing a condition that must be met for the specified redirect to be applied. If the routing rule does not include a condition, the rule is applied to all requests.
KeyPrefixEquals	<p>The prefix of the object key name from which requests are redirected.</p> <p><code>KeyPrefixEquals</code> is required if <code>HttpErrorCodeReturnedEquals</code> is not specified. If both <code>KeyPrefixEquals</code> and <code>HttpErrorCodeReturnedEquals</code> are specified, both must be true for the condition to be met.</p>
HttpErrorCodeReturnedEquals	<p>The HTTP error code that must match for the redirect to apply. If an error occurs, and if the error code meets this value, then the specified redirect applies.</p> <p><code>HttpErrorCodeReturnedEquals</code> is required if <code>KeyPrefixEquals</code> is not specified. If both <code>KeyPrefixEquals</code> and <code>HttpErrorCodeReturnedEquals</code> are specified, both must be true for the condition to be met.</p>
Redirect	

Name	Description
	Container element that provides instructions for redirecting the request. You can redirect requests to another host or another page, or you can specify another protocol to use. A <code>RoutingRule</code> must have a <code>Redirect</code> element. A <code>Redirect</code> element must contain at least one of the following sibling elements: <code>Protocol</code> , <code>HostName</code> , <code>ReplaceKeyPrefixWith</code> , <code>ReplaceKeyWith</code> , or <code>HttpRedirectCode</code> .
<code>Protocol</code>	The protocol, <code>http</code> or <code>https</code> , to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>Protocol</code> is not required.
<code>HostName</code>	The hostname to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>HostName</code> is not required.
<code>ReplaceKeyPrefixWith</code>	The prefix of the object key name that replaces the value of <code>KeyPrefixEquals</code> in the redirect request. If one of its siblings is supplied, <code>ReplaceKeyPrefixWith</code> is not required. It can be supplied only if <code>ReplaceKeyWith</code> is not supplied.
<code>ReplaceKeyWith</code>	The object key to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>ReplaceKeyWith</code> is not required. It can be supplied only if <code>ReplaceKeyPrefixWith</code> is not supplied.

Name	Description
HttpRedirectCode	The HTTP redirect code to be used in the <code>Location</code> header that is returned in the response. If one of its siblings is supplied, <code>HttpRedirectCode</code> is not required.

Redirection rules examples

The following examples explain common redirection tasks:

Important

To create redirection rules in the new Amazon S3 console, you must use JSON.

Example 1: Redirect after renaming a key prefix

Suppose that your bucket contains the following objects:

- index.html
- docs/article1.html
- docs/article2.html

You decide to rename the folder from `docs/` to `documents/`. After you make this change, you need to redirect requests for prefix `docs/` to `documents/`. For example, request for `docs/article1.html` will be redirected to `documents/article1.html`.

In this case, you add the following routing rule to the website configuration.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "docs/"  
    },
```

```
        "Redirect": {  
            "ReplaceKeyPrefixWith": "documents/"  
        }  
    }  
]
```

XML

```
<RoutingRules>  
  <RoutingRule>  
    <Condition>  
      <KeyPrefixEquals>docs/</KeyPrefixEquals>  
    </Condition>  
    <Redirect>  
      <ReplaceKeyPrefixWith>documents/</ReplaceKeyPrefixWith>  
    </Redirect>  
  </RoutingRule>  
</RoutingRules>
```

Example 2: Redirect requests for a deleted folder to a page

Suppose that you delete the `images/` folder (that is, you delete all objects with the key prefix `images/`). You can add a routing rule that redirects requests for any object with the key prefix `images/` to a page named `folderdeleted.html`.

JSON

```
[  
  {  
    "Condition": {  
      "KeyPrefixEquals": "images/"  
    },  
    "Redirect": {  
      "ReplaceKeyWith": "folderdeleted.html"  
    }  
  }  
]
```

XML

```
<RoutingRules>
```

```
<RoutingRule>
<Condition>
    <KeyPrefixEquals>images/</KeyPrefixEquals>
</Condition>
<Redirect>
    <ReplaceKeyWith>folderdeleted.html</ReplaceKeyWith>
</Redirect>
</RoutingRule>
</RoutingRules>
```

Example 3: Redirect for an HTTP error

Suppose that when a requested object is not found, you want to redirect requests to an Amazon Elastic Compute Cloud (Amazon EC2) instance. Add a redirection rule so that when an HTTP status code 404 (Not Found) is returned, the site visitor is redirected to an Amazon EC2 instance that handles the request.

The following example also inserts the object key prefix report-404/ in the redirect. For example, if you request a page ExamplePage.html and it results in an HTTP 404 error, the request is redirected to a page report-404/ExamplePage.html on the specified Amazon EC2 instance. If there is no routing rule and the HTTP error 404 occurs, the error document that is specified in the configuration is returned.

JSON

```
[{
    {
        "Condition": {
            "HttpErrorCodeReturnedEquals": "404"
        },
        "Redirect": {
            "HostName": "ec2-11-22-333-44.compute-1.amazonaws.com",
            "ReplaceKeyPrefixWith": "report-404/"
        }
    }
}]
```

XML

```
<RoutingRules>
<RoutingRule>
```

```
<Condition>
  <HttpErrorCodeReturnedEquals>404</HttpErrorCodeReturnedEquals >
</Condition>
<Redirect>
  <HostName>ec2-11-22-333-44.compute-1.amazonaws.com</HostName>
  <ReplaceKeyPrefixWith>report-404/</ReplaceKeyPrefixWith>
</Redirect>
</RoutingRule>
</RoutingRules>
```

Redirect requests for an object

You can redirect requests for an object to another object or URL by setting the website redirect location in the metadata of the object. You set the redirect by adding the `x-amz-website-redirect-location` property to the object metadata. On the Amazon S3 console, you set the **Website Redirect Location** in the metadata of the object. If you use the [Amazon S3 API](#), you set `x-amz-website-redirect-location`. The website then interprets the object as a 301 redirect.

To redirect a request to another object, you set the redirect location to the key of the target object. To redirect a request to an external URL, you set the redirect location to the URL that you want. For more information about object metadata, see [System-defined object metadata](#).

When you set a page redirect, you can either keep or delete the source object content. For example, if you have a `page1.html` object in your bucket, you can redirect any requests for this page to another object, `page2.html`. You have two options:

- Keep the content of the `page1.html` object and redirect page requests.
- Delete the content of `page1.html` and upload a zero-byte object named `page1.html` to replace the existing object and redirect page requests.

Using the S3 console

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you have configured as a static website (for example, `example.com`).
3. Under **Objects**, select your object.
4. Choose **Actions**, and choose **Edit metadata**.

5. Choose **Metadata**.
6. Choose **Add Metadata**.
7. Under **Type**, choose **System Defined**.
8. In **Key**, choose **x-amz-website-redirect-location**.
9. In **Value**, enter the key name of the object that you want to redirect to, for example, /page2.html.

For another object in the same bucket, the / prefix in the value is required. You can also set the value to an external URL, for example, http://www.example.com.

10. Choose **Edit metadata**.

Using the REST API

The following Amazon S3 API actions support the x-amz-website-redirect-location header in the request. Amazon S3 stores the header value in the object metadata as x-amz-website-redirect-location.

- [PUT Object](#)
- [Initiate Multipart Upload](#)
- [POST Object](#)
- [PUT Object - Copy](#)

A bucket configured for website hosting has both the website endpoint and the REST endpoint. A request for a page that is configured as a 301 redirect has the following possible outcomes, depending on the endpoint of the request:

- **Region-specific website endpoint** – Amazon S3 redirects the page request according to the value of the x-amz-website-redirect-location property.
- **REST endpoint** – Amazon S3 doesn't redirect the page request. It returns the requested object.

For more information about the endpoints, see [Key differences between a website endpoint and a REST API endpoint](#).

When setting a page redirect, you can either keep or delete the object content. For example, suppose that you have a page1.html object in your bucket.

- To keep the content of page1.html and only redirect page requests, you can submit a [PUT Object - Copy](#) request to create a new page1.html object that uses the existing page1.html object as the source. In your request, you set the x-amz-website-redirect-location header. When the request is complete, you have the original page with its content unchanged, but Amazon S3 redirects any requests for the page to the redirect location that you specify.
- To delete the content of the page1.html object and redirect requests for the page, you can send a PUT Object request to upload a zero-byte object that has the same object key: page1.html. In the PUT request, you set x-amz-website-redirect-location for page1.html to the new object. When the request is complete, page1.html has no content, and requests are redirected to the location that is specified by x-amz-website-redirect-location.

When you retrieve the object using the [GET Object](#) action, along with other object metadata, Amazon S3 returns the x-amz-website-redirect-location header in the response.

Using cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section provides an overview of CORS. The subtopics describe how you can enable CORS using the Amazon S3 console, or programmatically by using the Amazon S3 REST API and the AWS SDKs.

Cross-origin resource sharing: Use-case scenarios

The following are example scenarios for using CORS.

Scenario 1

Suppose that you are hosting a website in an Amazon S3 bucket named website as described in [Hosting a static website using Amazon S3](#). Your users load the website endpoint:

`http://website.s3-website.us-east-1.amazonaws.com`

Now you want to use JavaScript on the webpages that are stored in this bucket to be able to make authenticated GET and PUT requests against the same bucket by using the Amazon S3

API endpoint for the bucket, `website.s3.us-east-1.amazonaws.com`. A browser would normally block JavaScript from allowing those requests, but with CORS you can configure your bucket to explicitly enable cross-origin requests from `website.s3-website.us-east-1.amazonaws.com`.

Scenario 2

Suppose that you want to host a web font from your S3 bucket. Again, browsers require a CORS check (also called a preflight check) for loading web fonts. You would configure the bucket that is hosting the web font to allow any origin to make these requests.

How does Amazon S3 evaluate the CORS configuration on a bucket?

When Amazon S3 receives a preflight request from a browser, it evaluates the CORS configuration for the bucket and uses the first CORSRule rule that matches the incoming browser request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

 **Note**

The ACLs and policies continue to apply when you enable CORS on your bucket.

How Object Lambda Access Point supports CORS

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `"AllowedOrigins": "*"` header field.

For more information about using CORS, see the following topics.

Topics

- [Elements of a CORS configuration](#)
- [Configuring cross-origin resource sharing \(CORS\)](#)
- [Testing CORS](#)
- [Troubleshooting CORS](#)

Elements of a CORS configuration

To configure your bucket to allow cross-origin requests, you create a CORS configuration. The CORS configuration is a document with elements that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. You can add up to 100 rules to the configuration. You can add the CORS configuration as the `cors` subresource to the bucket.

If you are configuring CORS in the S3 console, you must use JSON to create a CORS configuration. The new S3 console only supports JSON CORS configurations.

For more information about the CORS configuration and the elements in it, see the topics below. For instructions on how to add a CORS configuration, see [Configuring cross-origin resource sharing \(CORS\)](#).

Important

In the S3 console, the CORS configuration must be JSON.

Topics

- [AllowedMethods element](#)
- [AllowedOrigins element](#)
- [AllowedHeaders element](#)
- [ExposeHeaders element](#)
- [MaxAgeSeconds element](#)
- [Examples of CORS configurations](#)

AllowedMethods element

In the CORS configuration, you can specify the following values for the AllowedMethods element.

- GET
- PUT
- POST
- DELETE
- HEAD

AllowedOrigins element

In the AllowedOrigins element, you specify the origins that you want to allow cross-domain requests from, for example, `http://www.example.com`. The origin string can contain only one * wildcard character, such as `http://*.example.com`. You can optionally specify * as the origin to enable all the origins to send cross-origin requests. You can also specify `https` to enable only secure origins.

AllowedHeaders element

The AllowedHeaders element specifies which headers are allowed in a preflight request through the `Access-Control-Request-Headers` header. Each header name in the `Access-Control-Request-Headers` header must match a corresponding entry in the element. Amazon S3 will send only the allowed headers in a response that were requested. For a sample list of headers that can be used in requests to Amazon S3, go to [Common Request Headers](#) in the *Amazon Simple Storage Service API Reference* guide.

Each AllowedHeaders string in your configuration can contain at most one * wildcard character. For example, `<AllowedHeader>x-amz-*</AllowedHeader>` will enable all Amazon-specific headers.

ExposeHeaders element

Each ExposeHeader element identifies a header in the response that you want customers to be able to access from their applications (for example, from a JavaScript XMLHttpRequest object). For a list of common Amazon S3 response headers, go to [Common Response Headers](#) in the *Amazon Simple Storage Service API Reference* guide.

MaxAgeSeconds element

The MaxAgeSeconds element specifies the time in seconds that your browser can cache the response for a preflight request as identified by the resource, the HTTP method, and the origin.

Examples of CORS configurations

Instead of accessing a website by using an Amazon S3 website endpoint, you can use your own domain, such as example1.com to serve your content. For information about using your own domain, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

The following example CORS configuration has three rules, which are specified as `CORSRule` elements:

- The first rule allows cross-origin PUT, POST, and DELETE requests from the `http://www.example1.com` origin. The rule also allows all headers in a preflight OPTIONS request through the `Access-Control-Request-Headers` header. In response to preflight OPTIONS requests, Amazon S3 returns requested headers.
- The second rule allows the same cross-origin requests as the first rule, but the rule applies to another origin, `http://www.example2.com`.
- The third rule allows cross-origin GET requests from all origins. The `*` wildcard character refers to all origins.

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "PUT",  
      "POST",  
      "DELETE"  
    ],  
    "AllowedOrigins": [  
      "http://www.example1.com"  
    ],  
    "ExposeHeaders": []  
  },  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "GET"  
    ]  
  }]
```

```
        "PUT",
        "POST",
        "DELETE"
    ],
    "AllowedOrigins": [
        "http://www.example2.com"
    ],
    "ExposeHeaders": []
},
{
    "AllowedHeaders": [],
    "AllowedMethods": [
        "GET"
    ],
    "AllowedOrigins": [
        "*"
    ],
    "ExposeHeaders": []
}
]
```

XML

```
<CORSConfiguration>
<CORSRule>
    <AllowedOrigin>http://www.example1.com</AllowedOrigin>

    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>

    <AllowedHeader>*</AllowedHeader>
</CORSRule>
<CORSRule>
    <AllowedOrigin>http://www.example2.com</AllowedOrigin>

    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>

    <AllowedHeader>*</AllowedHeader>
</CORSRule>
<CORSRule>
```

```
<AllowedOrigin>*</AllowedOrigin>
<AllowedMethod>GET</AllowedMethod>
</CORSRule>
</CORSConfiguration>
```

The CORS configuration also allows optional configuration parameters, as shown in the following CORS configuration. In this example, the CORS configuration allows cross-origin PUT, POST, and DELETE requests from the `http://www.example.com` origin.

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "*"  
    ],  
    "AllowedMethods": [  
      "PUT",  
      "POST",  
      "DELETE"  
    ],  
    "AllowedOrigins": [  
      "http://www.example.com"  
    ],  
    "ExposeHeaders": [  
      "x-amz-server-side-encryption",  
      "x-amz-request-id",  
      "x-amz-id-2"  
    ],  
    "MaxAgeSeconds": 3000  
  }  
]
```

XML

```
<CORSConfiguration>
  <CORSRule>
    <AllowedOrigin>http://www.example.com</AllowedOrigin>
    <AllowedMethod>PUT</AllowedMethod>
    <AllowedMethod>POST</AllowedMethod>
    <AllowedMethod>DELETE</AllowedMethod>
    <AllowedHeader>*</AllowedHeader>
```

```
<MaxAgeSeconds>3000</MaxAgeSeconds>
<ExposeHeader>x-amz-server-side-encryption</
ExposeHeader>
<ExposeHeader>x-amz-request-id</
ExposeHeader>
<ExposeHeader>x-amz-id-2</ExposeHeader>
</CORSRule>
</CORSConfiguration>
```

The CORSRule element in the preceding configuration includes the following optional elements:

- **MaxAgeSeconds**—Specifies the amount of time in seconds (in this example, 3000) that the browser caches an Amazon S3 response to a preflight OPTIONS request for the specified resource. By caching the response, the browser does not have to send preflight requests to Amazon S3 if the original request will be repeated.
- **ExposeHeaders**—Identifies the response headers (in this example, `x-amz-server-side-encryption`, `x-amz-request-id`, and `x-amz-id-2`) that customers are able to access from their applications (for example, from a JavaScript XMLHttpRequest object).

Configuring cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section shows you how to enable CORS using the Amazon S3 console, the Amazon S3 REST API, and the AWS SDKs. To configure your bucket to allow cross-origin requests, you add a CORS configuration to the bucket. A CORS configuration is a document that defines rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) supported for each origin, and other operation-specific information. In the S3 console, the CORS configuration must be a JSON document.

For example CORS configurations in JSON and XML, see [Elements of a CORS configuration](#).

Using the S3 console

This section explains how to use the Amazon S3 console to add a cross-origin resource sharing (CORS) configuration to an S3 bucket.

When you enable CORS on the bucket, the access control lists (ACLs) and other access permission policies continue to apply.

Important

In the S3 console, the CORS configuration must be JSON. For examples CORS configurations in JSON and XML, see [Elements of a CORS configuration](#).

To add a CORS configuration to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a bucket policy for.
4. Choose **Permissions**.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the **CORS configuration editor** text box, type or copy and paste a new CORS configuration, or edit an existing configuration.

The CORS configuration is a JSON file. The text that you type in the editor must be valid JSON. For more information, see [Elements of a CORS configuration](#).

7. Choose **Save changes**.

Note

Amazon S3 displays the Amazon Resource Name (ARN) for the bucket next to the **CORS configuration editor** title. For more information about ARNs, see [Amazon Resource Names \(ARNs\) and AWS Service Namespaces](#) in the *Amazon Web Services General Reference*.

Using the AWS SDKs

You can use the AWS SDK to manage cross-origin resource sharing (CORS) for a bucket. For more information about CORS, see [Using cross-origin resource sharing \(CORS\)](#).

The following examples:

- Creates a CORS configuration and sets the configuration on a bucket
- Retrieves the configuration and modifies it by adding a rule
- Adds the modified configuration to the bucket
- Deletes the configuration

Java

Example

Example

For instructions on how to create and test a working sample, see [Getting Started](#) in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;

    BucketCrossOriginConfiguration configuration = new
BucketCrossOriginConfiguration();
    configuration.setRules(rules);

    try {
        AmazonS3 s3Client = AmazonS3ClientBuilder.standard()
            .withCredentials(new ProfileCredentialsProvider())
            .withRegion(clientRegion)
            .build();

        // Add the configuration to the bucket.
        s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

        // Retrieve and display the configuration.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        printCORSConfiguration(configuration);

        // Add another new rule.
        List<CORSRule.AllowedMethods> rule3AM = new
ArrayList<CORSRule.AllowedMethods>();
        rule3AM.add(CORSRule.AllowedMethods.HEAD);
        CORSRule rule3 = new
CORSRule().withId("CORSRule3").withAllowedMethods(rule3AM)
    .withAllowedOrigins(Arrays.asList("http://www.example.com"));

        rules = configuration.getRules();
        rules.add(rule3);
```

```
        configuration.setRules(rules);
        s3Client.setBucketCrossOriginConfiguration(bucketName, configuration);

        // Verify that the new rule was added by checking the number of rules in
the
        // configuration.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        System.out.println("Expected # of rules = 3, found " +
configuration.getRules().size());

        // Delete the configuration.
        s3Client.deleteBucketCrossOriginConfiguration(bucketName);
        System.out.println("Removed CORS configuration.");

        // Retrieve and display the configuration to verify that it was
        // successfully deleted.
        configuration = s3Client.getBucketCrossOriginConfiguration(bucketName);
        printCORSConfiguration(configuration);
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it, so it returned an error response.
        e.printStackTrace();
    } catch (SdkClientException e) {
        // Amazon S3 couldn't be contacted for a response, or the client
        // couldn't parse the response from Amazon S3.
        e.printStackTrace();
    }
}

private static void printCORSConfiguration(BucketCrossOriginConfiguration
configuration) {
    if (configuration == null) {
        System.out.println("Configuration is null.");
    } else {
        System.out.println("Configuration has " +
configuration.getRules().size() + " rules\n");

        for (CORSRule rule : configuration.getRules()) {
            System.out.println("Rule ID: " + rule.getId());
            System.out.println("MaxAgeSeconds: " + rule.getMaxAgeSeconds());
            System.out.println("AllowedMethod: " + rule.getAllowedMethods());
            System.out.println("AllowedOrigins: " + rule.getAllowedOrigins());
            System.out.println("AllowedHeaders: " + rule.getAllowedHeaders());
            System.out.println("ExposeHeader: " + rule.getExposedHeaders());
        }
    }
}
```

```
        System.out.println();
    }
}
}
}
```

.NET

Example

For information about setting up and running the code examples, see [Getting Started with the AWS SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class CORSTest
    {
        private const string bucketName = "**** bucket name ****";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
RegionEndpoint.USWest2;
        private static IAmazonS3 s3Client;

        public static void Main()
        {

            Console.WriteLine("ExposeHeader: {0}", string.Join(", ",
rule.ExposeHeaders.ToArray()));
        }
    }
}
```

Using the REST API

To set a CORS configuration on your bucket, you can use the AWS Management Console. If your application requires it, you can also send REST requests directly. The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API actions related to the CORS configuration:

- [PutBucketCors](#)
- [GetBucketCors](#)
- [DeleteBucketCors](#)
- [OPTIONS object](#)

Testing CORS

To test your CORS configuration, a CORS preflight request can be sent with the OPTIONS method so that the server can respond if it is acceptable to send the request. When Amazon S3 receives a preflight request, S3 evaluates the CORS configuration for the bucket and uses the first CORSRule rule that matches the incoming request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The Origin header in a CORS request to your bucket must match the origins in the AllowedOrigins element in your CORS configuration.
- The HTTP methods that are specified in the Access-Control-Request-Method in a CORS request to your bucket must match the method or methods listed in the AllowedMethods element in your CORS configuration.
- The headers listed in the Access-Control-Request-Headers header in a preflight request must match the headers in the AllowedHeaders element in your CORS configuration.

The following is an example of a CORS configuration. To create a CORS Configuration, see [Configuring CORS](#). For more examples of a CORS configuration, see [Elements of a CORS configuration](#).

JSON

```
[  
  {  
    "AllowedHeaders": [  
      "
```

```
        "Authorization"  
    ],  
    "AllowedMethods": [  
        "GET"  
        "PUT",  
        "POST",  
        "DELETE"  
    ],  
    "AllowedOrigins": [  
        "http://www.example1.com"  
    ],  
    "ExposeHeaders": [  
        "x-amz-meta-custom-header"  
    ]  
  
}  
]
```

To test the CORS configuration, you can send a preflight OPTIONS check by using the following CURL command. CURL is a command-line tool that can be used to interact with S3. For more information, see [CURL](#).

```
curl -v -X OPTIONS \  
-H "Origin: http://www.example1.com" \  
-H "Access-Control-Request-Method: PUT" \  
-H "Access-Control-Request-Headers: Authorization" \  
-H "Access-Control-Expose-Headers: x-amz-meta-custom-header"\ \  
"http://bucket_name.s3.amazonaws.com/object_prefix_name"
```

In the above example, the curl -v -x OPTIONS command is used to send a preflight request to S3 to inquire if it is allowed by S3 to send a PUT request on an object from the cross origin http://www.example1.com. The headers Access-Control-Request-Headers and Access-Control-Expose-Headers are optional.

- In response to the Access-Control-Request-Method header in the preflight OPTIONS request, Amazon S3 returns the list of allowed methods if the requested methods match.
- In response to the Access-Control-Request-Headers header in the preflight OPTIONS request, Amazon S3 returns the list of allowed headers if the requested headers match.

- In response to the Access-Control-Expose-Headers header in the preflight OPTIONS request, Amazon S3 returns a list of allowed headers if the requested headers match the allowed headers that can be accessed by scripts running in the browser.

Note

When sending a preflight request, if any of the CORS request headers are not allowed, none of the response CORS headers are returned.

In response to this preflight OPTIONS request, you will receive a 200 OK response. For common error codes received when testing CORS and more information to solve CORS related issues, see [Troubleshooting CORS](#).

```
< HTTP/1.1 200 OK
< Date: Fri, 12 Jul 2024 00:23:51 GMT
< Access-Control-Allow-Origin: http://www.example1.com
< Access-Control-Allow-Methods: GET, PUT, POST, DELETE
< Access-Control-Allow-Headers: Authorization
< Access-Control-Expose-Headers: x-amz-meta-custom-header
< Access-Control-Allow-Credentials: true
< Vary: Origin, Access-Control-Request-Headers, Access-Control-Request-Method
< Server: AmazonS3
< Content-Length: 0
```

Troubleshooting CORS

The following topics can help you troubleshoot some common CORS issues related to S3.

Topics

- [403 Forbidden error: CORS is not enabled for this bucket](#)
- [403 Forbidden error: This CORS request is not allowed](#)
- [Headers not found in CORS response](#)
- [Considerations of CORS on S3 proxy integrations](#)

403 Forbidden error: CORS is not enabled for this bucket

The following 403 Forbidden error occurs when a cross-origin request is sent to Amazon S3 but CORS is not configured on your S3 bucket.

Error: HTTP/1.1 403 Forbidden CORS Response: CORS is not enabled for this bucket.

The CORS configuration is a document or policy with rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. See how to [configure CORS](#) on S3 by using the Amazon S3 console, AWS SDKs, and REST API. For more information on CORS and examples of a CORS configuration, see [Elements of CORS](#).

403 Forbidden error: This CORS request is not allowed

The following 403 Forbidden error is received when a CORS rule in your CORS configuration doesn't match the data in your request.

Error: HTTP/1.1 403 Forbidden CORS Response: This CORS request is not allowed.

As a result, this 403 Forbidden error can occur for multiple reasons:

- Origin is not allowed.
- Methods are not allowed.
- Requested headers are not allowed.

For each request that Amazon S3 receives, you must have a CORS rule in your CORS configuration that matches the data in your request.

Origin is not allowed

The Origin header in a CORS request to your bucket must match the origins in the AllowedOrigins element in your CORS configuration. A wildcard character ("*") in the AllowedOrigins element would match all HTTP methods. For more information on how to update the AllowedOrigins element, see [Configuring cross-origin resource sharing \(CORS\)](#).

For example, if only the `http://www.example1.com` domain is included in the AllowedOrigins element, then a CORS request sent from the `http://www.example2.com` domain would receive the 403 Forbidden error.

The following example shows part of a CORS configuration that includes the `http://www.example1.com` domain in the `AllowedOrigins` element.

```
"AllowedOrigins": [  
    "http://www.example1.com"  
]
```

For a CORS request sent from the `http://www.example2.com` domain to be successful, the `http://www.example2.com` domain should be included in the `AllowedOrigins` element of CORS configuration.

```
"AllowedOrigins": [  
    "http://www.example1.com"  
    "http://www.example2.com"  
]
```

Methods are not allowed

The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration. A wildcard character ("`*`") in `AllowedMethods` would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see [Configuring cross-origin resource sharing \(CORS\)](#).

In a CORS configuration, you can specify the following methods in the `AllowedMethods` element:

- GET
- PUT
- POST
- DELETE
- HEAD

The following example shows part of a CORS configuration that includes the `GET` method in the `AllowedMethods` element. Only requests including the `GET` method would succeed.

```
"AllowedMethods": [  
    "GET"
```

]

If an HTTP method (for example, PUT) was used in a CORS request or included in a pre-flight CORS request to your bucket but the method isn't present in your CORS configuration, the request would result in a 403 Forbidden error. To allow this CORS request or CORS pre-flight request, the PUT method must be added to your CORS configuration.

```
"AllowedMethods": [  
    "GET"  
    "PUT"  
]
```

Requested headers are not allowed

The headers listed in the Access-Control-Request-Headers header in a pre-flight request must match the headers in the AllowedHeaders element in your CORS configuration. For a list of common headers that can be used in requests to Amazon S3, see [Common Request Headers](#). For more information on how to update the AllowedHeaders element, see [Configuring cross-origin resource sharing \(CORS\)](#).

The following example shows part of a CORS configuration that includes the Authorization header in the AllowedHeaders element. Only requests for the Authorization header would succeed.

```
"AllowedHeaders": [  
    "Authorization"  
]
```

If a header (for example Content-MD5 was included in a CORS request but the header isn't present in your CORS configuration, the request would result in a 403 Forbidden error. To allow this CORS request , the Content-MD5 header must be added to your CORS configuration. If you want to pass both Authorization and Content-MD5 headers in a CORS request to your bucket, confirm that both headers are included in the AllowedHeaders element in your CORS configuration.

```
"AllowedHeaders": [  
    "Authorization"  
    "Content-MD5"
```

]

Headers not found in CORS response

The `ExposeHeaders` element in your CORS configuration identifies which response headers that you would like to make accessible to scripts and applications running in browsers, in response to a CORS request.

If your objects stored in your S3 bucket have user-defined metadata (for example, `x-amz-meta-custom-header`) along with the response data, this custom header could contain additional metadata or information that you want to access from your client-side JavaScript code. However, by default, browsers block access to custom headers for security reasons. To allow your client-side JavaScript to access custom headers, you need to include the header in your CORS configuration.

In the example below, the `x-amz-meta-custom-header1` header is included in the `ExposeHeaders` element. The `x-amz-meta-custom-header2` isn't included in the `ExposeHeaders` element and is missing from the CORS configuration. In the response, only the values included in the `ExposeHeaders` element would be returned. If the request included the `x-amz-meta-custom-header2` header in the `Access-Control-Expose-Headers` header, the response would still return a `200 OK`. However, only the permitted header, For example `x-amz-meta-custom-header1` would be returned and show in the response.

```
"ExposeHeaders": [  
    "x-amz-meta-custom-header1"  
]
```

To ensure all headers appear in the response, add all permitted headers to the `ExposeHeaders` element in your CORS configuration as shown below.

```
"ExposeHeaders": [  
    "x-amz-meta-custom-header1",  
    "x-amz-meta-custom-header2"  
]
```

Considerations of CORS on S3 proxy integrations

If you are experiencing errors and have already checked the CORS configuration on your S3 bucket, and the cross-origin request is sent to proxies such as AWS CloudFront, try the following:

- Configure the settings to allow the `OPTIONS` method for HTTP requests.

- Configure the proxy to forward the following headers: Origin, Access-Control-Request-Headers, and Access-Control-Request-Method.

Some proxies provide pre-defined features for CORS requests. For example, in CloudFront, you can configure a policy that includes the headers

that enable cross-origin resource sharing (CORS) requests when the origin is an Amazon S3 bucket.

This policy has the following settings:

- Headers included in origin requests:

Origin

Access-Control-Request-Headers

Access-Control-Request-Method

- Cookies included in origin requests: None
- Query strings included in origin requests: None

For more information, see [Control origin requests with a policy](#) and [Use managed origin request policies](#) in the *CloudFront Developer Guide*.

Static website tutorials

The following tutorials or walkthroughs present complete procedures for how to create and configure an Amazon S3 general purpose bucket for static website hosting and hosting on-demand video streaming. The purpose of these tutorials is to provide general guidance. These tutorials are intended for a lab-type environment, and they use example bucket names, user names, and so on. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

- [Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#) – You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. After your video is packaged into the right formats, you can store it on a server or in an S3 general purpose bucket, and then deliver it with CloudFront as viewers request it. In this tutorial, you will learn how to configure your general purpose bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain

Name System (DNS) and custom domain management. CloudFront serves the video from its cache, retrieving it from your general purpose bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see [Optimizing caching and availability](#) in the *Amazon CloudFront Developer Guide*.

- [**Configuring a static website**](#) – You can configure a general purpose bucket to function like a website. This tutorial walks you through the steps of hosting a website on Amazon S3 including creating a bucket, enabling static website hosting in the S3 console, creating an index document and creating an error document. For more information, see [Hosting a static website using Amazon S3](#).
- [**Configuring a static website using a custom domain registered with Route 53**](#) – You can create and configure a general purpose bucket to host a static website and create redirects on S3 for a website with a custom domain name that is registered with Amazon Route 53. You use Route 53 to register domains and to define where you want to route internet traffic for your domain. This tutorial shows how to create Route 53 alias records that routes traffic for your domain and subdomain to your general purpose bucket that contains an HTML file. For more information, see [Use your domain for a static website in an Amazon S3 bucket](#) in the *Amazon Route 53 Developer Guide*. After you complete this tutorial, you can optionally use CloudFront to improve the performance of your website. For more information, see [Speeding up your website with Amazon CloudFront](#).
- [**Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket**](#) – We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information, see [Deploying a static website from S3 using the Amplify console](#) in the *AWS Amplify Hosting User Guide*.

Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53

You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. Video on demand (VOD) streaming means that your video content is stored on a server and viewers can watch it at any time.

CloudFront is a fast, highly secure, and programmable content delivery network (CDN) service. CloudFront can deliver your content securely over HTTPS from all of the CloudFront edge locations around the globe. For more information about CloudFront, see [What is Amazon CloudFront?](#) in the *Amazon CloudFront Developer Guide*.

CloudFront caching reduces the number of requests that your origin server must respond to directly. When a viewer (end user) requests a video that you serve with CloudFront, the request is routed to a nearby edge location closer to where the viewer is located. CloudFront serves the video from its cache, retrieving it from the S3 bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see [Optimizing caching and availability](#) in the *Amazon CloudFront Developer Guide*.

Objective

In this tutorial, you configure an S3 bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management.

Topics

- [Prerequisites: Register and configure a custom domain with Route 53](#)
- [Step 1: Create an S3 bucket](#)
- [Step 2: Upload a video to the S3 bucket](#)
- [Step 3: Create a CloudFront origin access identity](#)
- [Step 4: Create a CloudFront distribution](#)
- [Step 5: Access the video through the CloudFront distribution](#)
- [Step 6: Configure your CloudFront distribution to use your custom domain name](#)
- [Step 7: Access the S3 video through the CloudFront distribution with the custom domain name](#)
- [\(Optional\) Step 8: View data about requests received by your CloudFront distribution](#)
- [Step 9: Clean up](#)
- [Next steps](#)

Prerequisites: Register and configure a custom domain with Route 53

Before you start this tutorial, you must register and configure a custom domain (for example, **example.com**) with Route 53 so that you can configure your CloudFront distribution to use a custom domain name later.

Without a custom domain name, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

`https://CloudFront distribution domain name/Path to an S3 video`

For example, `https://d111111abcdef8.cloudfront.net/sample.mp4`.

After you configure your CloudFront distribution to use a custom domain name configured with Route 53, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

<https://CloudFront distribution alternate domain name/Path to an S3 video>

For example, <https://www.example.com/sample.mp4>. A custom domain name is simpler and more intuitive for your viewers to use.

To register a custom domain, see [Registering a new domain using Route 53](#) in the *Amazon Route 53 Developer Guide*.

When you register a domain name with Route 53, Route 53 creates the hosted zone for you, which you will use later in this tutorial. This hosted zone is where you store information about how to route traffic for your domain, for example, to an Amazon EC2 instance or a CloudFront distribution.

There are fees associated with domain registration, your hosted zone, and DNS queries received by your domain. For more information, see [Amazon Route 53 Pricing](#).

 **Note**

When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*.

Step 1: Create an S3 bucket

Create a bucket to store the original video that you plan to stream.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

 **Note**

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket (for example, **tutorial-bucket**).

For more information about naming buckets in Amazon S3, see [General purpose bucket naming rules](#).

6. For **Region**, choose the AWS Region where you want the bucket to reside.

If possible, you should pick the Region that is closest to the majority of your viewers. For more information about the bucket Region, see [Buckets overview](#).

7. For **Block Public Access settings for this bucket**, keep the default settings (**Block all public access** is enabled).

Even with **Block all public access** enabled, viewers can still access the uploaded video through CloudFront. This feature is a major advantage of using CloudFront to host a video stored in S3.

We recommend that you keep all settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see [Blocking public access to your Amazon S3 storage](#).

8. For the remaining settings, keep the defaults.

(Optional) If you want to configure additional bucket settings for your specific use case, see [Creating a bucket](#).

9. Choose **Create bucket**.

Step 2: Upload a video to the S3 bucket

The following procedure describes how to upload a video file to an S3 bucket by using the console. If you're uploading many large video files to S3, you might want to use [Amazon S3 Transfer Acceleration](#) to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

To upload a file to the bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**.

For example, you can upload a video file named sample.mp4.
7. Choose **Upload**.

Step 3: Create a CloudFront origin access identity

To restrict direct access to the video from your S3 bucket, create a special CloudFront user called an origin access identity (OAI). You will associate the OAI with your distribution later in this tutorial. By using an OAI, you make sure that viewers can't bypass CloudFront and get the video directly from the S3 bucket. Only the CloudFront OAI can access the file in the S3 bucket. For more information, see [Restricting access to Amazon S3 content by using an OAI](#) in the *Amazon CloudFront Developer Guide*.

To create a CloudFront OAI

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, under the **Security** section, choose **Origin access**.
3. Under the **Identities** tab, choose **Create origin access identity**.
4. Enter a name (for example, **S3-OAI**) for the new origin access identity.
5. Choose **Create**.

Step 4: Create a CloudFront distribution

To use CloudFront to serve and distribute the video in your S3 bucket, you must create a CloudFront distribution.

Substeps

- [Create a CloudFront distribution](#)

- [Review the bucket policy](#)

Create a CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. Choose **Create distribution**.
4. In the **Origin** section, for **Origin domain**, choose the domain name of your S3 origin, which starts with the name of the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
5. For **Origin access**, choose **Legacy access identities**.
6. Under **Origin access identity**, choose the origin access identity that you created in [Step 3](#) (for example, **S3-0AI**).
7. Under **Bucket policy**, choose **Yes, update the bucket policy**.
8. In the **Default cache behavior** section, under **Viewer protocol policy**, choose **Redirect HTTP to HTTPS**.

When you choose this feature, HTTP requests are automatically redirected to HTTPS to secure your website and protect your viewers' data.

9. For the other settings in the **Default cache behaviors** section, keep the default values.

(Optional) You can control how long your file stays in a CloudFront cache before CloudFront forwards another request to your origin. Reducing the duration allows you to serve dynamic content. Increasing the duration means that your viewers get better performance because your files are more likely to be served directly from the edge cache. A longer duration also reduces the load on your origin. For more information, see [Managing how long content stays in the cache \(expiration\)](#) in the *Amazon CloudFront Developer Guide*.

10. For the other sections, keep the remaining settings set to the defaults.

For more information about the different settings options, see [Values That You Specify When You Create or Update a Distribution](#) in the *Amazon CloudFront Developer Guide*.

11. At the bottom of the page, choose **Create distribution**.

12. On the **General** tab for your CloudFront distribution, under **Details**, the value of the **Last modified** column for your distribution changes from **Deploying** to the timestamp when the distribution was last modified. This process typically takes a few minutes.

Review the bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you used earlier as the origin of your CloudFront distribution (for example, **tutorial-bucket**).
4. Choose the **Permissions** tab.
5. In the **Bucket policy** section, confirm that you see a statement similar to the following in the bucket policy text:

```
{  
    "Version": "2008-10-17",  
    "Id": "PolicyForCloudFrontPrivateContent",  
    "Statement": [  
        {  
            "Sid": "1",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access  
Identity EH1HDMB1FH2TC"  
            },  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::tutorial-bucket/*"  
        }  
    ]  
}
```

This is the statement that your CloudFront distribution added to your bucket policy when you chose **Yes, update the bucket policy** earlier.

This bucket policy update indicates that you successfully configured the CloudFront distribution to restrict access to the S3 bucket. Because of this restriction, objects in the bucket can be accessed only through your CloudFront distribution.

Step 5: Access the video through the CloudFront distribution

Now, CloudFront can serve the video stored in your S3 bucket. To access your video through CloudFront, you must combine your CloudFront distribution domain name with the path to the video in the S3 bucket.

To create a URL to the S3 video using the CloudFront distribution domain name

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. To get the distribution domain name, do the following:
 - a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - b. After finding the distribution in the list, widen the **Domain name** column to copy the domain name value for your CloudFront distribution.
4. In a new browser tab, paste the distribution domain name that you copied.
5. Return to the previous browser tab, and open the S3 console at <https://console.aws.amazon.com/s3/>.
6. In the left navigation pane, choose **Buckets**.
7. In the **Buckets** list, choose the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
8. In the **Objects** list, choose the name of the video that you uploaded in [Step 2](#) (for example, **sample.mp4**).
9. On the object detail page, in the **Object overview** section, copy the value of the **Key**. This value is the path to the uploaded video object in the S3 bucket.
10. Return to the browser tab where you previously pasted the distribution domain name, enter a forward slash (/) after the distribution domain name, and then paste the path to the video that you copied earlier (for example, **sample.mp4**).

Now, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

`https://CloudFront distribution domain name/Path to the S3 video`

Replace *CloudFront distribution domain name* and *Path to the S3 video* with the appropriate values. An example URL is <https://d111111abcdef8.cloudfront.net/sample.mp4>.

Step 6: Configure your CloudFront distribution to use your custom domain name

To use your own domain name instead of the CloudFront domain name in the URL to access the S3 video, add an alternate domain name to your CloudFront distribution.

Substeps

- [Request an SSL certificate](#)
- [Add the alternate domain name to your CloudFront distribution](#)
- [Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name](#)
- [Check whether IPv6 is enabled for your distribution and create another DNS record if needed](#)

Request an SSL certificate

To allow your viewers to use HTTPS and your custom domain name in the URL for your video streaming, use AWS Certificate Manager (ACM) to request a Secure Sockets Layer (SSL) certificate. The SSL certificate establishes an encrypted network connection to the website.

1. Sign in to the AWS Management Console and open the ACM console at <https://console.aws.amazon.com/acm/>.
2. If the introductory page appears, under **Provision certificates**, choose **Get Started**.
3. On the **Request a certificate** page, choose **Request a public certificate**, and then choose **Request a certificate**.
4. On the **Add domain names** page, enter the fully qualified domain name (FQDN) of the site that you want to secure with an SSL/TLS certificate. You can use an asterisk (*) to request a wildcard certificate to protect several site names in the same domain. For this tutorial, enter * and the custom domain name that you configured in [Prerequisites](#). For example, enter *.example.com, and then choose **Next**.

For more information, see [To request an ACM public certificate \(console\)](#) in the *AWS Certificate Manager User Guide*.

5. On the **Select validation method** page, choose **DNS validation**. Then, choose **Next**.

If you are able to edit your DNS configuration, we recommend that you use DNS domain validation rather than email validation. DNS validation has multiple benefits over email validation. For more information, see [Option 1: DNS validation](#) in the *AWS Certificate Manager User Guide*.

6. (Optional) On the **Add tags** page, tag your certificate with metadata.
7. Choose **Review**.
8. On the **Review** page, verify that the information under **Domain name** and **Validation method** are correct. Then, choose **Confirm and request**.

The **Validation** page shows that your request is being processed and that the certificate domain is being validated. The certificate awaiting validation is in the **Pending validation** status.

9. On the **Validation** page, choose the down arrow to the left of your custom domain name, and then choose **Create record in Route 53** to validate your domain ownership through DNS.

Doing this adds a CNAME record provided by AWS Certificate Manager to your DNS configuration.

10. In the **Create record in Route 53** dialog box, choose **Create**.

The **Validation** page should display a status notification of **Success** at the bottom.

11. Choose **Continue** to view the **Certificates** list page.

The **Status** for your new certificate changes from **Pending validation** to **Issued** within 30 minutes.

Add the alternate domain name to your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. Choose the ID for the distribution that you created in [Step 4](#).
4. On the **General** tab, go to the **Settings** section, and choose **Edit**.

5. On the **Edit settings** page, for **Alternate domain name (CNAME) - optional**, choose **Add item** to add the custom domain names that you want to use in the URL for the S3 video served by this CloudFront distribution.

In this tutorial, for example, if you want to route traffic for a subdomain, such as `www.example.com`, enter the subdomain name (`www`) with the domain name (`example.com`). Specifically, enter **www.example.com**.

 **Note**

The alternate domain name (CNAME) that you add must be covered by the SSL certificate that you previously attached to your CloudFront distribution.

6. For **Custom SSL certificate - optional**, choose the SSL certificate that you requested earlier (for example, `*.example.com`).

 **Note**

If you don't see the SSL certificate immediately after you request it, wait 30 minutes, and then refresh the list until the SSL certificate is available for you to select.

7. Keep the remaining settings set to the defaults. Choose **Save changes**.
8. On the **General** tab for the distribution, wait for the value of **Last modified** to change from **Deploying** to the timestamp when the distribution was last modified.

Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
4. Choose **Create record**, and then use the **Quick create record** method.
5. For **Record name**, keep the value for the record name the same as the alternate domain name of the CloudFront distribution that you added earlier.

In this tutorial, to route traffic to a subdomain, such as `www.example.com`, enter the subdomain name without the domain name. For example, enter only `www` in the text field before your custom domain name.

6. For **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Value**, choose the **Alias** toggle to enable the alias resource.
8. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
9. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in [Step 4](#).

To find the domain name of your CloudFront distribution, do the following:

- a. In a new browser tab, sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v3/home>.
 - b. In the left navigation pane, choose **Distributions**.
 - c. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - d. After finding the distribution in the list, widen the **Domain name** column to see the domain name value for your CloudFront distribution.
10. On the **Create record** page in the Route 53 console, for the remaining settings, keep the defaults.
 11. Choose **Create records**.

Check whether IPv6 is enabled for your distribution and create another DNS record if needed

If IPv6 is enabled for your distribution, you must create another DNS record.

1. To check whether IPv6 is enabled for your distribution, do the following:
 - a. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
 - b. In the left navigation pane, choose **Distributions**.
 - c. Choose the ID of the CloudFront distribution that you created in [Step 4](#).
 - d. On the **General** tab, under **Settings**, check whether **IPv6** is set to **Enabled**.

If IPv6 is enabled for your distribution, you must create another DNS record.

2. If IPv6 is enabled for your distribution, do the following to create a DNS record:
 - a. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
 - b. In the left navigation pane, choose **Hosted zones**.
 - c. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
 - d. Choose **Create record**, and then use the **Quick create record** method.
 - e. For **Record name**, in the text field before your custom domain name, type the same value that you typed when you created the IPv4 DNS record earlier. For example, in this tutorial, to route traffic for the subdomain `www.example.com`, enter only `www`.
 - f. For **Record type**, choose **AAAA - Routes traffic to an IPv6 address and some AWS resources**.
 - g. For **Value**, choose the **Alias** toggle to enable the alias resource.
 - h. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
 - i. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in [Step 4](#).
 - j. For the remaining settings, keep the defaults.
 - k. Choose **Create records**.

Step 7: Access the S3 video through the CloudFront distribution with the custom domain name

To access the S3 video using the custom URL, you must combine your alternate domain name with the path to the video in the S3 bucket.

To create a custom URL to access the S3 video through the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. To get the alternate domain name of your CloudFront distribution, do the following:

- a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
 - b. After finding the distribution in the list, widen the **Alternate domain names** column to copy the value of the alternate domain name of your CloudFront distribution.
4. In a new browser tab, paste the alternate domain name of the CloudFront distribution.
 5. Return to the previous browser tab, and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 6. Find the path to your S3 video, as explained in [Step 5](#).
 7. Return to the browser tab where you previously pasted the alternate domain name, enter a forward slash (/), and then paste the path to your S3 video (for example, sample.mp4).

Now, your S3 video is publicly accessible and hosted through CloudFront at a custom URL that looks similar to the following:

`https://CloudFront distribution alternate domain name/Path to the S3 video`

Replace *CloudFront distribution alternate domain name* and *Path to the S3 video* with the appropriate values. An example URL is <https://www.example.com/sample.mp4>.

(Optional) Step 8: View data about requests received by your CloudFront distribution

To view data about requests received by your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, under **Reports & analytics**, choose the reports from the console, ranging from **Cache statistics**, **Popular Objects**, **Top Referrers**, **Usage**, and **Viewers**.

You can filter each report dashboard. For more information, see [CloudFront Reports in the Console](#) in the *Amazon CloudFront Developer Guide*.

3. To filter data, choose the ID of the CloudFront distribution that you created in [Step 4](#).

Step 9: Clean up

If you hosted an S3 streaming video using CloudFront and Route 53 only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

Note

When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*.

Substeps

- [Delete the CloudFront distribution](#)
- [Delete the DNS record](#)
- [Delete the public hosted zone for your custom domain](#)
- [Delete the custom domain name from Route 53](#)
- [Delete the original video in the S3 source bucket](#)
- [Delete the S3 source bucket](#)

Delete the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. In the left navigation pane, choose **Distributions**.
3. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
4. To delete the CloudFront distribution, you must disable it first.
 - If the value of the **Status** column is **Enabled** and the value of **Last modified** is the timestamp when the distribution was last modified, continue to disable the distribution before deleting it.
 - If the value of **Status** is **Enabled** and the value of **Last modified** is **Deploying**, wait until the value of **Status** changes to the timestamp when the distribution was last modified. Then continue to disable the distribution before deleting it.

5. To disable the CloudFront distribution, do the following:

- a. In the **Distributions** list, select the check box next to the ID for the distribution that you want to delete.
- b. To disable the distribution, choose **Disable**, and then choose **Disable** to confirm.

If you disable a distribution that has an alternate domain name associated with it, CloudFront stops accepting traffic for that domain name (such as `www.example.com`), even if another distribution has an alternate domain name with a wildcard (*) that matches the same domain (such as `*.example.com`).

- c. The value of **Status** immediately changes to **Disabled**. Wait until the value of **Last modified** changes from **Deploying** to the timestamp when the distribution was last modified.

Because CloudFront must propagate this change to all edge locations, it might take a few minutes before the update is complete and the **Delete** option is available for you to delete the distribution.

6. To delete the disabled distribution, do the following:

- a. Choose the check box next to the ID for the distribution that you want to delete.
- b. Choose **Delete**, and then choose **Delete** to confirm.

Delete the DNS record

If you want to delete the public hosted zone for the domain (including the DNS record), see [Delete the public hosted zone for your custom domain](#) in the *Amazon Route 53 Developer Guide*. If you only want to delete the DNS record created in [Step 6](#), do the following:

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in [Prerequisites](#) (for example, `example.com`).
4. In the list of records, select the check box next to the records that you want to delete (the records that you created in [Step 6](#)).

Note

You can't delete records that have a **Type** value of **NS** or **SOA**.

5. Choose **Delete records**.
6. To confirm the deletion, choose **Delete**.

Changes to records take time to propagate to the Route 53 DNS servers. Currently, the only way to verify that your changes have propagated is to use the [GetChange API action](#). Changes usually propagate to all Route 53 name servers within 60 seconds.

Delete the public hosted zone for your custom domain

Warning

If you want to keep your domain registration but stop routing internet traffic to your website or web application, we recommend that you delete records in the hosted zone (as described in the prior section) instead of deleting the hosted zone.

If you delete a hosted zone, someone else can use the domain and route traffic to their own resources using your domain name.

In addition, if you delete a hosted zone, you can't undelete it. You must create a new hosted zone and update the name servers for your domain registration, which can take up to 48 hours to take effect.

If you want to make the domain unavailable on the internet, you can first transfer your DNS service to a free DNS service and then delete the Route 53 hosted zone. This prevents future DNS queries from possibly being misrouted.

1. If the domain is registered with Route 53, see [Adding or changing name servers and glue records for a domain](#) in the *Amazon Route 53 Developer Guide* for information about how to replace Route 53 name servers with name servers for the new DNS service.
2. If the domain is registered with another registrar, use the method provided by the registrar to change name servers for the domain.

Note

If you're deleting a hosted zone for a subdomain (`www.example.com`), you don't need to change name servers for the domain (`example.com`).

1. Sign in to the AWS Management Console and open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that you want to delete.
4. On the **Records** tab for your hosted zone, confirm that the hosted zone that you want to delete contains only an **NS** and an **SOA** record.

If it contains additional records, delete them first.

If you created any NS records for subdomains in the hosted zone, delete those records too.

5. On the **DNSSEC signing** tab for your hosted zone, disable DNSSEC signing if it was enabled. For more information, see [Disabling DNSSEC signing](#) in the *Amazon Route 53 Developer Guide*.
6. At the top of the details page of the hosted zone, choose **Delete zone**.
7. To confirm the deletion, enter **delete**, and then choose **Delete**.

Delete the custom domain name from Route 53

For most top-level domains (TLDs), you can delete the registration if you no longer want it. If you delete a domain name registration from Route 53 before the registration is scheduled to expire, AWS does not refund the registration fee. For more information, see [Deleting a domain name registration](#) in the *Amazon Route 53 Developer Guide*.

⚠ Important

If you want to transfer the domain between AWS accounts or transfer the domain to another registrar, don't delete the domain and expect to immediately reregister it. Instead, see the applicable documentation in the *Amazon Route 53 Developer Guide*:

- [Transferring a domain to a different AWS account](#)

- [Transferring a domain from Amazon Route 53 to another registrar](#)

Delete the original video in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the video to in [Step 2](#) (for example, **tutorial-bucket**).
4. On the **Objects** tab, select the check box next to the name of the object that you want to delete (for example, `sample.mp4`).
5. Choose **Delete**.
6. Under **Permanently delete objects?**, enter **permanently delete** to confirm that you want to delete this object.
7. Choose **Delete objects**.

Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, select the option button next to the name of the bucket that you created in [Step 1](#) (for example, **tutorial-bucket**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Next steps

After you complete this tutorial, you can further explore the following related use cases:

- Transcode S3 videos into streaming formats needed by a particular television or connected device before hosting these videos with a CloudFront distribution.

To use Amazon S3 Batch Operations, AWS Lambda and AWS Elemental MediaConvert to batch-transcode a collection of videos to a variety of output media formats, see [Tutorial: Batch-transcoding videos with S3 Batch Operations](#).

- Host other objects stored in S3, such as images, audio, motion graphics, style sheets, HTML, JavaScript, React apps, and so on, using CloudFront and Route 53.

For example, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#) and [Speeding up your website with Amazon CloudFront](#).

- Use [Amazon S3 Transfer Acceleration](#) to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. Transfer Acceleration improves transfer performance by routing traffic through the CloudFront globally distributed edge locations and over the AWS backbone networks. It also uses network protocol optimizations. For more information, see [Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration](#).

Tutorial: Configuring a static website on Amazon S3

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see [Default encryption FAQ](#).

You can configure an Amazon S3 bucket to function like a website. This example walks you through the steps of hosting a website on Amazon S3.

Important

The following tutorial requires disabling Block Public Access. We recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled

and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks. For more information, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Step 1: Create a bucket](#)
- [Step 2: Enable static website hosting](#)
- [Step 3: Edit Block Public Access settings](#)
- [Step 4: Add a bucket policy that makes your bucket content publicly available](#)
- [Step 5: Configure an index document](#)
- [Step 6: Configure an error document](#)
- [Step 7: Test your website endpoint](#)
- [Step 8: Clean up](#)

Step 1: Create a bucket

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see [Creating a bucket](#).

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose **Create bucket**.
3. Enter the **Bucket name** (for example, `example.com`).
4. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

5. To accept the default settings and create the bucket, choose **Create**.

Step 2: Enable static website hosting

After you create a bucket, you can enable static website hosting for your bucket. You can create a new bucket or use an existing bucket.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Step 3: Edit Block Public Access settings

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#)

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 4: Add a bucket policy that makes your bucket content publicly available

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

⚠ Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Step 5: Configure an index document

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.

5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:
 - Drag and drop the index file into the console bucket listing.
 - Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Step 6: Configure an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, `404.html`). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, 404.html). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Step 7: Test your website endpoint

After you configure static website hosting for your bucket, you can test your website endpoint.

Note

Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.

For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

Your index document opens in a separate browser window.

You now have a website hosted on Amazon S3. This website is available at the Amazon S3 website endpoint. However, you might have a domain, such as example.com, that you want to use to serve the content from the website you created. You might also want to use Amazon S3 root domain support to serve requests for both http://www.example.com and http://example.com. This requires additional steps. For an example, see [Tutorial: Configuring a static website using a custom domain registered with Route 53](#).

Step 8: Clean up

If you created your static website only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available. For more information, see [Deleting a bucket](#).

Tutorial: Configuring a static website using a custom domain registered with Route 53

Suppose that you want to host a static website on Amazon S3. You've registered a domain with Amazon Route 53 (for example, example.com), and you want requests for `http://www.example.com` and `http://example.com` to be served from your Amazon S3 content. You can use this walkthrough to learn how to host a static website and create redirects on Amazon S3 for a website with a custom domain name that is registered with Route 53. You can work with an existing website that you want to host on Amazon S3, or use this walkthrough to start from scratch.

After you complete this walkthrough, you can optionally use Amazon CloudFront to improve the performance of your website. For more information, see [Speeding up your website with Amazon CloudFront](#).

Note

Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For a tutorial about how to host your content securely with CloudFront and Amazon S3, see [Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53](#). For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

Automating static website setup with an AWS CloudFormation template

You can use an AWS CloudFormation template to automate your static website setup. The AWS CloudFormation template sets up the components that you need to host a secure static website so that you can focus more on your website's content and less on configuring components.

The AWS CloudFormation template includes the following components:

- Amazon S3 – Creates an Amazon S3 bucket to host your static website.
- CloudFront – Creates a CloudFront distribution to speed up your static website.
- Lambda@Edge – Uses [Lambda@Edge](#) to add security headers to every server response. Security headers are a group of headers in the web server response that tell web browsers to take extra security precautions. For more information, see the blog post [Adding HTTP security headers using Lambda@Edge and Amazon CloudFront](#).

This AWS CloudFormation template is available for you to download and use. For information and instructions, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Before you begin](#)
- [Step 1: Register a custom domain with Route 53](#)
- [Step 2: Create two buckets](#)
- [Step 3: Configure your root domain bucket for website hosting](#)
- [Step 4: Configure your subdomain bucket for website redirect](#)
- [Step 5: Configure logging for website traffic](#)
- [Step 6: Upload index and website content](#)
- [Step 7: Upload an error document](#)
- [Step 8: Edit S3 Block Public Access settings](#)
- [Step 9: Attach a bucket policy](#)
- [Step 10: Test your domain endpoint](#)
- [Step 11: Add alias records for your domain and subdomain](#)
- [Step 12: Test the website](#)
- [Speeding up your website with Amazon CloudFront](#)
- [Cleaning up your example resources](#)

Before you begin

As you follow the steps in this example, you work with the following services:

Amazon Route 53 – You use Route 53 to register domains and to define where you want to route internet traffic for your domain. The example shows how to create Route 53 alias records that

route traffic for your domain (example.com) and subdomain (www.example.com) to an Amazon S3 bucket that contains an HTML file.

Amazon S3 – You use Amazon S3 to create buckets, upload a sample website page, configure permissions so that everyone can see the content, and then configure the buckets for website hosting.

Step 1: Register a custom domain with Route 53

If you don't already have a registered domain name, such as example.com, register one with Route 53. For more information, see [Registering a new domain](#) in the *Amazon Route 53 Developer Guide*. After you register your domain name, you can create and configure your Amazon S3 buckets for website hosting.

Step 2: Create two buckets

To support requests from both the root domain and subdomain, you create two buckets.

- **Domain bucket** – example.com
- **Subdomain bucket** – www.example.com

These bucket names must match your domain name exactly. In this example, the domain name is example.com. You host your content out of the root domain bucket (example.com). You create a redirect request for the subdomain bucket (www.example.com). If someone enters www.example.com in their browser, they are redirected to example.com and see the content that is hosted in the Amazon S3 bucket with that name.

To create your buckets for website hosting

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see [Creating a bucket](#).

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Create your root domain bucket:
 - a. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

Note

To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see [AWS service endpoints](#) in the *Amazon Web Services General Reference*.

- b. In the left navigation pane, choose **General purpose buckets**.
- c. Choose **Create bucket**. The **Create bucket** page opens.
- d. Enter the **Bucket name** (for example, `example.com`).
- e. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

- f. To accept the default settings and create the bucket, choose **Create**.
3. Create your subdomain bucket:
 - a. Choose **Create bucket**.
 - b. Enter the **Bucket name** (for example, `www.example.com`).
 - c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see [Website endpoints](#).

- d. To accept the default settings and create the bucket, choose **Create**.

In the next step, you configure `example.com` for website hosting.

Step 3: Configure your root domain bucket for website hosting

In this step, you configure your root domain bucket (`example.com`) as a website. This bucket will contain your website content. When you configure a bucket for website hosting, you can access the website using the [Website endpoints](#).

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see [Configuring an index document](#).

9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see [Configuring a custom error document](#).

10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see [Configure redirection rules to use advanced conditional redirects](#).

11. Choose **Save changes**.

Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

After you [edit block public access settings](#) and [add a bucket policy](#) that allows public read access, you can use the website endpoint to access your website.

In the next step, you configure your subdomain (`www.example.com`) to redirect requests to your domain (`example.com`).

Step 4: Configure your subdomain bucket for website redirect

After you configure your root domain bucket for website hosting, you can configure your subdomain bucket to redirect all requests to the domain. In this example, all requests for `www.example.com` are redirected to `example.com`.

To configure a redirect request

1. On the Amazon S3 console, in the **General purpose buckets** list, choose your subdomain bucket name (`www.example.com` in this example).
2. Choose **Properties**.
3. Under **Static website hosting**, choose **Edit**.
4. Choose **Redirect requests for an object**.
5. In the **Target bucket** box, enter your root domain, for example, `example.com`.
6. For **Protocol**, choose `http`.
7. Choose **Save changes**.

Step 5: Configure logging for website traffic

If you want to track the number of visitors accessing your website, you can optionally enable logging for your root domain bucket. For more information, see [Logging requests with server access logging](#). If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging.

To enable server access logging for your root domain bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example logs.example.com.
3. Create a folder for the server access logging log files (for example, logs).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, cdn).

⚠ Important

When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the awslogsdelivery account FULL_CONTROL permissions to write logs to your bucket. For more information, see [Permissions required to configure standard logging and to access your log files](#) in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

5. In the **Buckets** list, choose your root domain bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:
 - Browse to the folder and bucket location:
 1. Choose **Browse S3**.
 2. Choose the bucket name, and then choose the logs folder.
 3. Choose **Choose path**.
 - Enter the S3 bucket path, for example, s3://logs.example.com/logs/.
10. Choose **Save changes**.

In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

Step 6: Upload index and website content

In this step, you upload your index document and optional website content to your root domain bucket.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

If you don't have an `index.html` file, you can use the following HTML to create one:

```
<html xmlns="http://www.w3.org/1999/xhtml" >
<head>
    <title>My Website Home Page</title>
</head>
<body>
    <h1>Welcome to my website</h1>
    <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see [Enabling website hosting](#).

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

- Drag and drop the index file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

8. (Optional) Upload other website content to your bucket.

Step 7: Upload an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **404.html**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see [Enabling website hosting](#) and [Configuring a custom error document](#).

After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see [Uploading objects](#).

Step 8: Edit S3 Block Public Access settings

In this example, you edit block public access settings for the domain bucket (example.com) to allow public access.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review [Blocking public access to your Amazon S3 storage](#) to ensure that you understand and accept the risks involved with allowing public access.

When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block all public access**, and choose **Save changes**.

Block public access (bucket settings)

Public access is granted to buckets and objects through access control lists (ACLs), bucket policies, access point policies, or all. In order to ensure that public access to all your S3 buckets and objects is blocked, turn on Block all public access. These settings apply only to this bucket and its access points. AWS recommends that you turn on Block all public access, but before applying any of these settings, ensure that your applications will work correctly without public access. If you require some level of public access to your buckets or objects within, you can customize the individual settings below to suit your specific storage use cases. [Learn more](#)

Account settings for Block Public Access are currently turned on

Account settings for Block Public Access that are enabled apply even if they are disabled for this bucket.

Block all public access

Turning this setting on is the same as turning on all four settings below. Each of the following settings are independent of one another.

Block public access to buckets and objects granted through new access control lists (ACLs)

S3 will block public access permissions applied to newly added buckets or objects, and prevent the creation of new public access ACLs for existing buckets and objects. This setting doesn't change any existing permissions that allow public access to S3 resources using ACLs.

Block public access to buckets and objects granted through any access control lists (ACLs)

S3 will ignore all ACLs that grant public access to buckets and objects.

Block public access to buckets and objects granted through new public bucket or access point policies

S3 will block new bucket and access point policies that grant public access to buckets and objects. This setting doesn't change any existing policies that allow public access to S3 resources.

Block public and cross-account access to buckets and objects through any public bucket or access point policies

S3 will ignore public and cross-account access for buckets or access points with policies that grant public access to buckets and objects.

Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to [edit the Block Public Access settings](#) for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 9: Attach a bucket policy

In this example, you attach a bucket policy to the domain bucket (example.com) to allow public read access. You replace the **Bucket-Name** in the example bucket policy with the name of your domain bucket, for example example.com.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

⚠ Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review [How can I secure the files in my Amazon S3 bucket?](#) to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublicReadGetObject",  
            "Effect": "Allow",  
            "Principal": "*",  
            "Action": [  
                "s3:GetObject"  
            ],  
            "Resource": [  
                "arn:aws:s3:::Bucket-Name/*"  
            ]  
        }  
    ]  
}
```

5. Update the Resource to your bucket name.

In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see [How do I add an S3 bucket policy?](#)

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

In the next step, you can figure out your website endpoints and test your domain endpoint.

Step 10: Test your domain endpoint

After you configure your domain bucket to host a public website, you can test your endpoint. For more information, see [Website endpoints](#). You can only test the endpoint for your domain bucket because your subdomain bucket is set up for website redirect and not static website hosting.

Note

Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.

For more information, see [How do I use CloudFront to serve a static website hosted on Amazon S3?](#) and [Requiring HTTPS for communication between viewers and CloudFront](#).

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

Your index document opens in a separate browser window.

In the next step, you use Amazon Route 53 to enable customers to use both of your custom URLs to navigate to your site.

Step 11: Add alias records for your domain and subdomain

In this step, you create the alias records that you add to the hosted zone for your domain maps `example.com` and `www.example.com`. Instead of using IP addresses, the alias records use the

Amazon S3 website endpoints. Amazon Route 53 maintains a mapping between the alias records and the IP addresses where the Amazon S3 buckets reside. You create two alias records, one for your root domain and one for your subdomain.

Add an alias record for your root domain and subdomain

To add an alias record for your root domain (`example.com`)

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.

 **Note**

If you don't already use Route 53, see [Step 1: Register a domain](#) in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create record**.
5. Choose **Switch to wizard**.

 **Note**

If you want to use quick create to create your alias records, see [Configuring Route 53 to route traffic to an S3 Bucket](#).

6. Choose **Simple routing**, and choose **Next**.
7. Choose **Define simple record**.
8. In **Record name**, accept the default value, which is the name of your hosted zone and your domain.
9. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
10. Choose the Region.
11. Choose the S3 bucket.

The bucket name should match the name that appears in the **Name** box. In the **Choose S3 bucket** list, the bucket name appears with the Amazon S3 website endpoint for the Region

where the bucket was created, for example, `s3-website-us-west-1.amazonaws.com` (`example.com`).

Choose S3 bucket lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2.amazonaws.com`. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the *Amazon Route 53 Developer Guide*.

12. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
13. For **Evaluate target health**, choose **No**.
14. Choose **Define simple record**.

To add an alias record for your subdomain (`www.example.com`)

1. Under **Configure records**, choose **Define simple record**.
2. In **Record name** for your subdomain, type `www`.
3. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
4. Choose the Region.
5. Choose the S3 bucket, for example, `s3-website-us-west-2.amazonaws.com` (`www.example.com`).

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2.amazonaws.com`. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the *Amazon Route 53 Developer Guide*.

6. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Evaluate target health**, choose **No**.
8. Choose **Define simple record**.

9. On the **Configure records** page, choose **Create records**.

Note

Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Add an alias record for your root domain and subdomain (old Route 53 console)

To add an alias record for your root domain (`example.com`)

The Route 53 console has been redesigned. In the Route 53 console you can temporarily use the old console. If you choose to work with the old Route 53 console, use the procedure below.

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.

Note

If you don't already use Route 53, see [Step 1: Register a domain](#) in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted Zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create Record Set**.
5. Specify the following values:

Name

Accept the default value, which is the name of your hosted zone and your domain.

For the root domain, you don't need to enter any additional information in the **Name** field.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose your bucket name.

The bucket name should match the name that appears in the **Name** box. In the **Alias Target** listing, the bucket name is followed by the Amazon S3 website endpoint for the Region where the bucket was created, for example example.com (s3-website-us-west-2.amazonaws.com). **Alias Target** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Alias Target** listing, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, s3-website-us-west-2. For a complete list of Amazon S3 website endpoints, see [Amazon S3 Website endpoints](#). For more information about the alias target, see [Value/route traffic to](#) in the [Amazon Route 53 Developer Guide](#).

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

6. Choose **Create**.

To add an alias record for your subdomain (www.example.com)

1. In the hosted zone for your root domain (example.com), choose **Create Record Set**.
2. Specify the following values:

Name

For the subdomain, enter www in the box.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose the same bucket name that appears in the **Name** field—for example, `www.example.com` (`s3-website-us-west-2.amazonaws.com`).

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

3. Choose **Create**.

Note

Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Step 12: Test the website

Verify that the website and the redirect work correctly. In your browser, enter your URLs. In this example, you can try the following URLs:

- **Domain** (`http://example.com`) – Displays the index document in the `example.com` bucket.
- **Subdomain** (`http://www.example.com`) – Redirects your request to `http://example.com`. You see the index document in the `example.com` bucket.

If your website or redirect links don't work, you can try the following:

- **Clear cache** – Clear the cache of your web browser.
- **Check name servers** – If your web page and redirect links don't work after you've cleared your cache, you can compare the name servers for your domain and the name servers for your hosted zone. If the name servers don't match, you might need to update your domain name servers to match those listed under your hosted zone. For more information, see [Adding or changing name servers and glue records for a domain](#).

After you've successfully tested your root domain and subdomain, you can set up an [Amazon CloudFront](#) distribution to improve the performance of your website and provide logs that you can use to review website traffic. For more information, see [Speeding up your website with Amazon CloudFront](#).

Speeding up your website with Amazon CloudFront

You can use [Amazon CloudFront](#) to improve the performance of your Amazon S3 website. CloudFront makes your website files (such as HTML, images, and video) available from data centers around the world (known as *edge locations*). When a visitor requests a file from your website, CloudFront automatically redirects the request to a copy of the file at the nearest edge location. This results in faster download times than if the visitor had requested the content from a data center that is located farther away.

CloudFront caches content at edge locations for a period of time that you specify. If a visitor requests content that has been cached for longer than the expiration date, CloudFront checks the origin server to see if a newer version of the content is available. If a newer version is available, CloudFront copies the new version to the edge location. Changes that you make to the original content are replicated to edge locations as visitors request the content.

Using CloudFront without Route 53

The tutorial on this page uses Route 53 to point to your CloudFront distribution. However, if you want to serve content hosted in an Amazon S3 bucket using CloudFront without using Route 53, see [Amazon CloudFront Tutorials: Setting up a Dynamic Content Distribution for Amazon S3](#). When you serve content hosted in an Amazon S3 bucket using CloudFront, you can use any bucket name, and both HTTP and HTTPS are supported.

Automating set up with an AWS CloudFormation template

For more information about using an AWS CloudFormation template to configure a secure static website that creates a CloudFront distribution to serve your website, see [Getting started with a secure static website](#) in the *Amazon CloudFront Developer Guide*.

Topics

- [Step 1: Create a CloudFront distribution](#)
- [Step 2: Update the record sets for your domain and subdomain](#)
- [\(Optional\) Step 3: Check the log files](#)

Step 1: Create a CloudFront distribution

First, you create a CloudFront distribution. This makes your website available from data centers around the world.

To create a distribution with an Amazon S3 origin

1. Open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. Choose **Create Distribution**.
3. On the **Create Distribution** page, in the **Origin Settings** section, for **Origin Domain Name**, enter the Amazon S3 website endpoint for your bucket—for example, **example.com.s3-website.us-west-1.amazonaws.com**.

CloudFront fills in the **Origin ID** for you.

4. For **Default Cache Behavior Settings**, keep the values set to the defaults.

With the default settings for **Viewer Protocol Policy**, you can use HTTPS for your static website. For more information these configuration options, see [Values that You Specify When You Create or Update a Web Distribution](#) in the *Amazon CloudFront Developer Guide*.

5. For **Distribution Settings**, do the following:
 - a. Leave **Price Class** set to **Use All Edge Locations (Best Performance)**.
 - b. Set **Alternate Domain Names (CNAMEs)** to the root domain and www subdomain. In this tutorial, these are example.com and www.example.com.

⚠️ Important

Before you perform this step, note the [requirements for using alternate domain names](#), in particular the need for a valid SSL/TLS certificate.

- c. For **SSL Certificate**, choose **Custom SSL Certificate (example.com)**, and choose the custom certificate that covers the domain and subdomain names.

For more information, see [SSL Certificate](#) in the *Amazon CloudFront Developer Guide*.

- d. In **Default Root Object**, enter the name of your index document, for example, `index.html`.

If the URL used to access the distribution doesn't contain a file name, the CloudFront distribution returns the index document. The **Default Root Object** should exactly match the name of the index document for your static website. For more information, see [Configuring an index document](#).

- e. Set **Logging** to **On**.

⚠️ Important

When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see [Permissions required to configure standard logging and to access your log files](#) in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

- f. For **Bucket for Logs**, choose the logging bucket that you created.

For more information about configuring a logging bucket, see [\(Optional\) Logging web traffic](#).

- g. If you want to store the logs that are generated by traffic to the CloudFront distribution in a folder, in **Log Prefix**, enter the folder name.
- h. Keep all other settings at their default values.

6. Choose **Create Distribution**.
7. To see the status of the distribution, find the distribution in the console and check the **Status** column.

A status of **InProgress** indicates that the distribution is not yet fully deployed.

After your distribution is deployed, you can reference your content with the new CloudFront domain name.

8. Record the value of **Domain Name** shown in the CloudFront console, for example, `dj4p1rv6mvubz.cloudfront.net`.
9. To verify that your CloudFront distribution is working, enter the domain name of the distribution in a web browser.

If your website is visible, the CloudFront distribution works. If your website has a custom domain registered with Amazon Route 53, you will need the CloudFront domain name to update the record set in the next step.

Step 2: Update the record sets for your domain and subdomain

Now that you have successfully created a CloudFront distribution, update the alias record in Route 53 to point to the new CloudFront distribution.

To update the alias record to point to a CloudFront distribution

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the left navigation, choose **Hosted zones**.
3. On the **Hosted Zones** page, choose the hosted zone that you created for your subdomain, for example, `www.example.com`.
4. Under **Records**, select the A record that you created for your subdomain.
5. Under **Record details**, choose **Edit record**.
6. Under **Route traffic to**, choose **Alias to CloudFront distribution**.
7. Under **Choose distribution**, choose the CloudFront distribution.
8. Choose **Save**.
9. To redirect the A record for the root domain to the CloudFront distribution, repeat this procedure for the root domain, for example, `example.com`.

The update to the record sets takes effect within 2–48 hours.

10. To see whether the new A records have taken effect, in a web browser, enter your subdomain URL, for example, `http://www.example.com`.

If the browser no longer redirects you to the root domain (for example, `http://example.com`), the new A records are in place. When the new A record has taken effect, traffic routed by the new A record to the CloudFront distribution is not redirected to the root domain. Any visitors who reference the site by using `http://example.com` or `http://www.example.com` are redirected to the nearest CloudFront edge location, where they benefit from faster download times.

 **Tip**

Browsers can cache redirect settings. If you think the new A record settings should have taken effect, but your browser still redirects `http://www.example.com` to `http://example.com`, try clearing your browser history and cache, closing and reopening your browser application, or using a different web browser.

(Optional) Step 3: Check the log files

The access logs tell you how many people are visiting the website. They also contain valuable business data that you can analyze with other services, such as [Amazon EMR](#).

CloudFront logs are stored in the bucket and folder that you choose when you create a CloudFront distribution and enable logging. CloudFront writes logs to your log bucket within 24 hours from when the corresponding requests are made.

To see the log files for your website

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the name of the logging bucket for your website.
3. Choose the CloudFront logs folder.
4. Download the .gzip files written by CloudFront before opening them.

If you created your website only as a learning exercise, you can delete the resources that you allocated so that you no longer accrue charges. To do so, see [Cleaning up your example resources](#). After you delete your AWS resources, your website is no longer available.

Cleaning up your example resources

If you created your static website as a learning exercise, you should delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available.

Tasks

- [Step 1: Delete the Amazon CloudFront distribution](#)
- [Step 2: Delete the Route 53 hosted zone](#)
- [Step 3: Disable logging and delete your S3 bucket](#)

Step 1: Delete the Amazon CloudFront distribution

Before you delete an Amazon CloudFront distribution, you must disable it. A disabled distribution is no longer functional and does not accrue charges. You can enable a disabled distribution at any time. After you delete a disabled distribution, it is no longer available.

To disable and delete a CloudFront distribution

1. Open the CloudFront console at <https://console.aws.amazon.com/cloudfront/v4/home>.
2. Select the distribution that you want to disable, and then choose **Disable**.
3. When prompted for confirmation, choose **Yes, Disable**.
4. Select the disabled distribution, and then choose **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Step 2: Delete the Route 53 hosted zone

Before you delete the hosted zone, you must delete the record sets that you created. You don't need to delete the NS and SOA records; these are automatically deleted when you delete the hosted zone.

To delete the record sets

1. Open the Route 53 console at <https://console.aws.amazon.com/route53/>.
2. In the list of domain names, select your domain name, and then choose **Go to Record Sets**.
3. In the list of record sets, select the A records that you created.

The type of each record set is listed in the **Type** column.

4. Choose **Delete Record Set**.
5. When prompted for confirmation, choose **Confirm**.

To delete a Route 53 hosted zone

1. Continuing from the previous procedure, choose **Back to Hosted Zones**.
2. Select your domain name, and then choose **Delete Hosted Zone**.
3. When prompted for confirmation, choose **Confirm**.

Step 3: Disable logging and delete your S3 bucket

Before you delete your S3 bucket, make sure that logging is disabled for the bucket. Otherwise, AWS continues to write logs to your bucket as you delete it.

To disable logging for a bucket

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Under **Buckets**, choose your bucket name, and then choose **Properties**.
3. From **Properties**, choose **Logging**.
4. Clear the **Enabled** check box.
5. Choose **Save**.

Now, you can delete your bucket. For more information, see [Deleting a bucket](#).

Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket

We recommend that you use [AWS Amplify Hosting](#) to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. Deploying a static website using Amplify Hosting provides you with the following benefits and features:

- **Deployment to the AWS content delivery network (CDN) powered by Amazon CloudFront -** CloudFront is a web service that speeds up distribution of your static and dynamic web content to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance, increased reliability and availability. For more information, see [How CloudFront delivers content](#) in the *Amazon CloudFront Developer Guide*.
- **HTTPS support** - Provides secure communication and data transfer between your website and a user's web browser.
- **Custom domains** - Easily connect your website to a custom URL purchased from a domain registrar such as Amazon Route 53.
- **Custom SSL certificates** - When you set up your custom domain, you can use the default managed certificate that Amplify provisions for you or you can use your own custom certificate purchased from the third-party certificate authority of your choice.
- **Built in metrics and CloudWatch monitoring** - Monitor traffic, errors, data transfer, and latency for your website.
- **Password protection** - Restrict access to your website, by setting up a username and password requirement in the Amplify console.
- **Redirects and rewrites** - Create redirect and rewrite rules in the Amplify console to enable a web server to reroute navigation from one URL to another.

When you deploy your application from an Amazon S3 general purpose bucket to Amplify Hosting, AWS charges are based on Amplify's pricing model. For more information, see [AWS Amplify Pricing](#).

 **Important**

Amplify Hosting is not available in all of the AWS Regions where Amazon S3 is available. To deploy a static website to Amplify Hosting, the Amazon S3 general purpose bucket containing your website must be located in a region where Amplify is available. For the list of regions where Amplify is available, see [Amplify endpoints](#) in the *Amazon Web Services General Reference*.

You can start the deployment process from the Amazon S3 console, the Amplify console, the AWS CLI, or the AWS SDKs. You can only deploy to Amplify from a general purpose bucket located in your own account. Amplify doesn't support cross-account bucket access.

Use the following instructions to deploy a static website from an Amazon S3 general purpose bucket to Amplify Hosting starting from the Amazon S3 console.

Deploying a static website to Amplify from the S3 console

To deploy a static website from the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the general purpose bucket that contains the website you want to deploy to Amplify Hosting.
4. Choose the **Properties** tab.
5. Under **Static website hosting**, choose **Create Amplify app**. At this step, the deployment process will move to the Amplify console.
6. On the **Deploy with S3** page, do the following steps.
 - a. For **App name**, enter the name of your app or website.
 - b. For **Branch name**, enter the name of your app's backend.
 - c. For **S3 location of objects to host**, either enter the directory path to your general purpose bucket or choose **Browse S3** to locate and select it.
7. Choose **Save and deploy**.

Note

If you update any of the objects for a static website in your general purpose bucket hosted on Amplify, you must redeploy the application to Amplify Hosting to cause the changes to take effect. Amplify Hosting doesn't automatically detect changes to your bucket. For more information, see [Updating a static website deployed to Amplify from an S3 bucket](#) in the [AWS Amplify Hosting User Guide](#).

To start directly from the Amplify console, see [Deploying a static website from S3 using the Amplify console](#) in the *AWS Amplify Hosting User Guide*.

To get started using the AWS SDKs, see [Creating a bucket policy to deploy a static website from S3 using the AWS SDKs](#) in the *AWS Amplify Hosting User Guide*.

Quotas

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Amazon S3 quotas include number of general purpose buckets, directory buckets, access points and more. You can request an increase for some quotas, but not all quotas can be increased. These increases are not granted immediately, so it may take a couple of days for your increase to become effective.

For a list of Amazon S3 quotas and their default values see, [Amazon S3 quotas](#) in the *AWS General Reference*.

Quota increases

To request a quota increase

You can request a quota increase by using one of following options:

- From the AWS Management Console: Open the [Service Quotas console](#). In the navigation pane, choose **AWS services**. Select **Amazon S3**, select a quota, and follow the directions to request a quota increase. For instructions, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.
- From the AWS CLI: Use the [`request-service-quota-increase`](#) AWS CLI command. For instructions, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

Reference

In addition to the Amazon S3 console, you can work with Amazon S3 programmatically using the Amazon S3 REST APIs, AWS SDKs, or AWS Command Line Interface (AWS CLI).

- [Amazon Simple Storage Service API Reference](#)
- [Code examples](#) in the *Amazon Simple Storage Service API Reference*
- [AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.
- [AWS SDKs](#)

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	Tools for PowerShell code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples

AWS SDK for Swift	AWS SDK for Swift code examples

Document history

- **Current API version:** 2006-03-01

The following table describes the important changes in each release of the *Amazon Simple Storage Service API Reference* and the *Amazon S3 User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
<u>S3 Tables adds support for adding schemas when creating tables</u>	You can now use the S3 Tables CreateTable API operation to create tables with schemas by adding an optional metadata flag. For more information, see <u>Creating tables</u> .	January 30, 2025
<u>S3 Metadata</u>	Amazon S3 Metadata is now generally available. S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom	January 27, 2025

metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see [Accelerating data discovery with S3 Metadata](#).

[AWS managed policies – New policies](#)

S3 Tables added two new AWS managed policies.

December 6, 2024

[S3 Tables](#)

Amazon S3 Tables provide S3 storage that's optimized for analytics workloads, with features that improve query performance, reduce storage costs for tables, and simplify the operation of data lakes at scale. S3 Tables introduces a new bucket type: table buckets, which are purpose-built for storing Apache Iceberg tables as subresources. Table buckets provide higher transactions per second (TPS) and better query throughput compared to self-managed tables in S3 general purpose buckets. You can automatically integrate your table buckets with AWS analytics services, such as Athena, Amazon Redshift, Amazon QuickSight, and more. For more information, see [Working with Amazon S3 Tables and table buckets](#).

December 3, 2024

S3 Metadata Preview

Amazon S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see [Accelerating data discovery with S3 Metadata](#).

December 3, 2024

Storage Browser for S3

Storage Browser for S3 is an open source component that you can add to your web applications to provide your end users with a simple interface for data stored in S3. For more information, see [Storage Browser for S3](#).

December 1, 2024

<u>New Amazon S3 checksum algorithm and improved checksum integrity features</u>	Amazon S3 adds the CRC-64NVME checksum algorithm and improved checksum integrity features. For more information, see <u>Checking object integrity in Amazon S3</u> .	December 1, 2024
<u>Data residency workloads</u>	In Dedicated Local Zones, you can create S3 directory buckets to store data for your data residency and isolation use cases. For more information, see <u>Data residency workloads</u> .	December 1, 2024
<u>New condition keys to enforce conditional writes</u>	Amazon S3 adds new condition keys <code>s3:if-match</code> and <code>s3:if-none-match</code> to use in bucket policies to force clients to use the <code>If-None-Match</code> or <code>If-Match</code> HTTP header. For more information, see <u>Enforce conditional writes on Amazon S3 buckets</u> .	November 25, 2024

[New HTTP header for conditional writes to check if the object has changed](#)

Amazon S3 adds the If-Match HTTP header to check an object's entity tag (ETag) before writing an object for some API operations. With this header, Amazon S3 compares the provided ETag value with the ETag value of the object in S3. If the ETag values don't match, the operation fails. For more information, see [How to prevent object overwrites with conditional writes](#).

[Amazon Redshift now integrates with S3 Access Grants](#)

Amazon Redshift customers can now use S3 Access Grants to scale and manage permissions for their S3 data. This allows Amazon Redshift customers to scale S3 permissions for corporate identities by using AWS IAM Identity Center as well as for IAM users and groups. For more information, see [Amazon Redshift integration with Amazon S3 Access Grants](#).

November 25, 2024

November 15, 2024

<u>AWS Organizations member accounts can now regain access to accidentally locked Amazon S3 buckets</u>	<p>AWS Organizations member accounts can now use a simple process through AWS Identity and Access Management (IAM) to regain access to accidentally locked Amazon S3 buckets. For more information, see <u>Perform a privileged task on an AWS Organizations member account in the AWS Identity and Access Management User Guide</u>.</p>	November 14, 2024
<u>Resource control policies (RCPs), a new type of authorization policy in AWS Organizations is also available for Amazon S3 buckets</u>	<p>Resource control policies (RCPs), a new authorization policy managed in AWS Organizations can be used to set the maximum available permissions on Amazon S3 buckets within your entire organization. For more information, see <u>Resource control policies (RCPs) in the AWS Organizations User Guide</u>.</p>	November 13, 2024
<u>Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets</u>	<p>Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets. To view your bucket utilization or request an increase, visit the <u>Service Quotas console</u>.</p>	September 30, 2024

<u>New default minimum object size transition behavior for Amazon S3 Lifecycle configurations</u>	Amazon S3 now applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitioned to any storage class. To learn how to override this behavior, see <u>Allowing objects smaller than 128 KB to be transitioned</u> .	September 24, 2024
<u>Directory buckets now support SSE-KMS using customer managed keys.</u>	Directory buckets now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You have more options to encrypt and manage the security of your data in directory buckets. For more information, see <u>Data protection and encryption in directory buckets</u> .	September 17, 2024

[S3 Access Grants supports an API action that lists the caller's access grants](#)

IAM identities and IAM Identity Center corporate directory identities can now use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or corporate directory identity can access through S3 Access Grants, within a particular AWS account. For more information, see [List the caller's access grants.](#)

September 5, 2024

[Enhanced access denied error messages for same-account requests](#)

Amazon S3 now includes additional context in access denied (HTTP 403) `Forbidden` errors for requests made to resources within the same AWS account. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see [Troubleshoot access denied \(403 Forbidden\) errors in Amazon S3..](#)

August 21, 2024

[Amazon S3 supports using conditional writes for PutObject and CompleteMultipartUpload](#)

You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate there is no existing object with the same key name already in your bucket. For more information, see [Conditional requests](#).

[Amazon S3 no longer charges for several HTTP error codes](#)

Amazon S3 has completed a change so unauthorized requests that customers did not initiate are free of charge. For more information, see [Billing for Amazon S3 error responses](#).

[Amazon S3 Select is no longer available to new customers](#)

Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. [Learn more](#).

August 20, 2024

August 19, 2024

July 25, 2024

<u>Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key</u>	Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key to control whether users can include optional metadata fields in their reports. For more information, see Control S3 Inventory report configuration creation .	February 20, 2024
<u>IPv6 support for S3 on Outposts</u>	You can now access S3 on Outposts buckets using IPv6 via S3 on Outposts dual-stack endpoints. IPv6 support for S3 on Outposts allows you to manage your S3 on Outposts buckets and control plane resources over IPv6 networks.	January 16, 2024
<u>New high-performance, single-zone Amazon S3 storage class – S3 Express One Zone</u>	Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. For more information, see S3 Express One Zone .	November 28, 2023
<u>Mountpoint for Amazon S3 adds support for S3 Express One Zone</u>	You can now mount S3 Express One Zone directory buckets with Mountpoint .	November 28, 2023

<u>Lambda invocation schema version</u>	Amazon S3 Batch Operation s introduces a new Lambda invocation schema version for use with Batch Operations jobs that act on directory buckets. For more information, see <u>Using Lambda and Amazon S3 batch operations with directory buckets.</u>	November 28, 2023
<u>Import action for directory buckets</u>	Amazon S3 introduces the import action. Import is a streamlined method for creating Amazon S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For more information, see <u>Importing objects into a directory bucket.</u>	November 28, 2023
<u>Manage S3 access with S3 Access Grants</u>	Amazon S3 Access Grants enables you to manage data permissions at scale for AWS Identity and Access Management (IAM) principals in addition to directory identities from corporate directories such as Azure AD. You can now enforce least-privilege S3 permissions and easily scale those permissions based on your business needs. For more information, see <u>Managing access with S3 Access Grants.</u>	November 26, 2023

<u>Mountpoint for Amazon S3 adds caching feature</u>	With Mountpoint , you can now configure caching for repeatedly accessed data.	November 22, 2023
<u>Enhanced Amazon S3 Batch Operations manifest generation</u>	You can now direct Amazon S3 Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Creating an Amazon S3 Batch Operations job .	November 22, 2023
<u>Existing Amazon S3 buckets can now add Object Lock configurations</u>	You can now enable Object Lock on existing Amazon S3 bucket. You may set legal holds and retention periods for new or existing buckets. For more information, see Using Object Lock .	November 20, 2023
<u>S3 Storage Lens request metrics for prefixes</u>	S3 Storage Lens introduces request metrics for prefixes within an Amazon S3 bucket. For more information, see Metrics categories .	November 17, 2023

<u>Amazon S3 Storage Lens groups</u>	S3 Storage Lens introduce s Storage Lens groups, a custom defined filter for objects based on object metadata. For more information, see <u>Working with Amazon S3 Storage Lens groups</u> .	November 15, 2023
<u>New IAM policy</u>	S3 on Outposts introduce s AWSServiceRoleForS3OnOutposts , a service-linked role to help manage network resources for you. For more information, see <u>Using service-linked roles for S3 on Outposts</u> .	October 3, 2023
<u>Amazon S3 provides the Last-Modified time for delete markers</u>	Amazon S3 provides the Last-Modified time of delete markers in the response headers of S3 Head and Get API operations. For more information, see <u>Working with delete markers</u> .	September 27, 2023
<u>Amazon S3 update to AWS managed policy</u>	Amazon S3 added s3:Describe* permissions to AmazonS3ReadOnlyAccess . For more information, see <u>AWS managed policies for Amazon S3</u> .	August 11, 2023

[Improved start times for Standard restore requests made through S3 Batch Operations](#)

Standard retrievals for restore requests that are made through S3 Batch Operations now can start within minutes. For more information, see [Archive Retrieval Options](#).

August 9, 2023

[Added Mountpoint, a high-throughput client for mounting an Amazon S3 bucket as a local file system.](#)

With [Mountpoint](#), your applications can access objects stored in Amazon S3 through file operations, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.

August 9, 2023

[Dual-layer server-side encryption with AWS Key Management Service keys \(DSSE-KMS\)](#)

Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. For more information, see [Using dual-layer server-side encryption with AWS KMS keys](#).

June 13, 2023

[Amazon S3 enables S3 Block Public Access and disables S3 access control lists \(ACLs\) for all new buckets.](#)

Amazon S3 now automatically enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new S3 buckets in all AWS Regions. For more information, see [Blocking public access to your Amazon S3 storage](#) and [Controlling ownership of objects and disabling ACLs for your bucket](#).

April 27, 2023

[S3 Replication Operations Failed metric](#)

Amazon S3 adds new Amazon CloudWatch metric to monitor S3 Replication failures. For more information, see [Monitoring progress with replication metrics](#).

April 5, 2023

[Private DNS](#)

AWS PrivateLink for Amazon S3 now supports Private DNS. For more information, see [Private DNS](#).

March 14, 2023

[Cross-account access points support in the Amazon S3 console](#)

Amazon S3 now supports creating cross-account access points with the Amazon S3 console. For more information, see [Creating access points](#).

March 14, 2023

<u>Amazon S3 on Outposts supports S3 Replication on Outposts</u>	With local S3 Replicati on, you can automatically replicate objects to a single Outposts destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Outposts or within the same Outposts as the source bucket. For more information, see <u>Replicating objects for S3 on Outposts</u> .	March 14, 2023
<u>Amazon S3 Object Lambda Access Point alias</u>	When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For more information, see <u>How to use a bucket-style alias for your Object Lambda Access Point</u> .	March 14, 2023
<u>Amazon S3 Multi-Region Access Points cross-account support</u>	Amazon S3 now supports creating cross-account Multi-Region Access Points with the Amazon S3 console. For more information, see <u>Creating Multi-Region Access Points</u> .	March 14, 2023

<u>Cross-account access points</u>	Amazon S3 supports creating cross-account access points. You can create a cross-account access point by using the AWS Command Line Interface (AWS CLI) or the REST API <code>CreateAccessPoint</code> operation. For more information, see <u>Creating access points</u> .	November 30, 2022
<u>Amazon S3 supports failover controls for Amazon S3 Multi-Region Access Points</u>	Amazon S3 introduces failover control for Multi-Region Access Points. These controls let you shift S3 data access request traffic routed through an Amazon S3 Multi-Region Access Point to an alternate AWS Region within minutes to test and build highly available applications. For more information, see <u>Amazon S3 Multi-Region Access Point failover controls</u> .	November 28, 2022
<u>Amazon S3 Storage Lens increases organization-wide visibility with 34 new metrics</u>	S3 Storage Lens introduces 34 additional metrics to uncover deeper cost-optimization opportunities, identify data-protection best practices, and improve the performance of application workflows. For more information, see <u>S3 Storage Lens metrics</u> .	November 17, 2022

<u>Amazon S3 supports higher restore request rates for S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive</u>	Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.	November 15, 2022
<u>Amazon S3 on Outposts supports additional S3 Lifecycle actions and filters</u>	S3 on Outposts supports additional S3 Lifecycle rules to optimize capacity management. You can expire objects as they age or are replaced with newer versions. You can create a lifecycle rule for a whole bucket or a subset of objects in a bucket by filtering with prefixes, object tags, or object size. For more information, see <u>Creating and managing a lifecycle configuration</u> .	November 2, 2022
<u>S3 Replication support for SSE-C objects</u>	You can replicate objects that are created using server-side encryption with customer-provided keys. For more information about replicating encrypted objects, see <u>Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS)</u> .	October 24, 2022

<u>Amazon S3 on Outposts supports access point aliases</u>	With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For more information, see <u>Using a bucket-style alias for your S3 on Outposts bucket access point.</u>	October 21, 2022
<u>S3 Object Lambda supports the HeadObject , ListObjects , and ListObjectsV2 operations</u>	You can use custom code to modify the data returned by standard S3 GET, LIST, or HEAD requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see <u>Transforming objects with S3 Object Lambda.</u>	October 4, 2022

[Amazon S3 on Outposts supports S3 Versioning](#)

When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures. For more information, see [Managing S3 Versioning for your S3 on Outposts bucket](#).

September 21, 2022

[AWS Backup for Amazon S3](#)

AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see [Using AWS Backup for Amazon S3](#).

February 18, 2022

[Use S3 Batch Replication to replicate existing objects](#)

With S3 Batch Replication, you can replicate objects that existed before a replication configuration was in place. Replicating existing objects is done through the use of a Batch Operations job. S3 Batch Replication differs from live replication, which continuously and automatically copies new objects across Amazon S3 buckets. For more information, see [Replicating existing objects with S3 Batch Replication](#).

February 8, 2022

[Rename of S3 Glacier Flexible Retrieval](#)

The Glacier storage class has been renamed to S3 Glacier Flexible Retrieval. This change does not impact the API.

November 30, 2021

<u>New S3 Object Ownership setting to disable ACLs</u>	You can apply the bucket owner enforced setting for Object Ownership to disable ACLs for your bucket and the objects in it and take ownership of every object in your bucket. The bucket owner enforced setting simplifies access management for data stored in Amazon S3. For more information, see <u>Controlling ownership of objects and disabling ACLs for your bucket.</u>	November 30, 2021
<u>New S3 Intelligent-Tiering storage class</u>	S3 Intelligent-Tiering Archive Instant Access is an additional storage class under S3 Intelligent-Tiering. For more information, see <u>How S3 Intelligent-Tiering works.</u>	November 30, 2021
<u>New S3 Glacier Instant Retrieval storage class</u>	You can now place objects in the S3 Glacier Instant Retrieval storage class. For more information about this storage class, see <u>Using Amazon S3 storage classes.</u>	November 30, 2021

<u>AWS Backup for Amazon S3</u> <u>Preview</u>	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information see, <u>Using AWS Backup for Amazon S3</u> .	November 30, 2021
<u>AWS Identity and Access Management Access Analyzer for Amazon S3</u>	IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. To learn more about validating policies using IAM Access Analyzer, see <u>IAM Access Analyzer policy validation</u> in the <i>IAM User Guide</i> .	November 30, 2021
<u>New event types</u>	New event types added to Amazon S3 Event Notifications, see <u>Amazon S3 Event Notifications</u> .	November 29, 2021
<u>Enable Amazon EventBridge on buckets</u>	You can enable EventBridge on Amazon S3 buckets to send events to Amazon EventBridge, see <u>Using EventBridge</u> .	November 29, 2021
<u>New S3 Lifecycle filters</u>	You can create lifecycle rules based on object size or specify how many noncurrent object versions to keep. For more information, see <u>Examples of S3 Lifecycle configuration</u> .	November 23, 2021

[Publish Amazon S3 Storage](#)

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, like alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, the CloudWatch APIs enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information, see the [Monitor S3 Storage Lens metrics in CloudWatch](#).

November 22, 2021

[Lens metrics to Amazon CloudWatch](#)[Multi-Region Access Points](#)

You can use Multi-Region Access Points to create a global endpoint that applications can use to fulfill requests from Amazon S3 buckets located in multiple AWS Regions. You can use this Multi-Region Access Point to route data to a bucket with the lowest latency. For more information about Multi-Region Access Points and how to use them, see [Multi-Region Access Point in Amazon S3](#).

September 2, 2021

<u>Amazon S3 on Outposts adds direct local access for applications</u>	Run your applications outside the AWS Outposts virtual private cloud (VPC) and access your S3 on Outposts data. You can also access S3 on Outposts objects directly from your on-premises network. For more information about configuring S3 on Outposts endpoints using <u>customer-owned IP (CoIP) addresses</u> and accessing your objects by creating a <u>local gateway</u> from your on-premises network, see <u>Accessing Amazon S3 on Outposts using VPC-only access points</u> .	July 29, 2021
<u>Amazon S3 access point alias</u>	When you create an access point, Amazon S3 automatically generates an alias that you can use instead of a bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for any access point data plane operation. For more information, see <u>Using a bucket-style alias for your access point</u> .	July 26, 2021

<u>Amazon S3 Inventory and S3 Batch Operations support S3</u>	Amazon S3 Inventory and Batch Operations support identifying and copying existing objects with S3 Bucket Keys. S3 Bucket Keys accelerate the reduction of server-side encryption costs for existing objects. For more information, see <u>Amazon S3 Inventory and Batch Operations Copy object</u> .	June 3, 2021
<u>Amazon S3 Storage Lens metrics account snapshot</u>	The S3 Storage Lens account snapshot displays your total storage, object count, and average object size on the S3 console home (Buckets) page by summarizing metrics from your default dashboard. For more information, see <u>S3 Storage Lens metrics account snapshot</u> .	May 5, 2021
<u>Increased Amazon S3 on Outposts endpoint support</u>	S3 on Outposts now supports up to 100 endpoints per Outpost. For more information, see <u>S3 on Outposts network restrictions</u> .	April 29, 2021

<u>Amazon S3 on Outposts event notifications in Amazon CloudWatch Events</u>	You can use CloudWatch Events to create a rule to capture any S3 on Outposts API event and get notified through all supported CloudWatch targets. For more information, see <u>Receiving S3 on Outposts event notifications using CloudWatch Events.</u>	April 19, 2021
<u>S3 Object Lambda</u>	With S3 Object Lambda, you can add your own code to Amazon S3 GET requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by standard S3 GET requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see <u>Transforming objects.</u>	March 18, 2021

[AWS PrivateLink](#)

With AWS PrivateLink for Amazon S3, you can connect directly to S3 by using an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. Interface endpoints are directly accessible from applications that are on premises or in a different AWS Region. For more information, see [AWS PrivateLink for Amazon S3](#).

February 2, 2021

[Managing Amazon S3 on Outposts capacity with AWS CloudTrail](#)

S3 on Outposts management events are available through CloudTrail logs. For more information, see [Managing S3 on Outposts capacity with CloudTrail](#).

December 21, 2020

[Strong consistency](#)

Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 bucket in all AWS Regions. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists, Amazon S3 Object Tags, and object metadata (for example, HEAD object) are strongly consistent. For more information, see [Amazon S3 data consistency model](#).

December 1, 2020

<u>Amazon S3 replica modification sync</u>	Amazon S3 replica modification sync keeps object metadata, such as tags, ACLs, and Object Lock settings, in sync between source objects and replicas. When this feature is enabled, Amazon S3 replicates metadata changes made to either the source object or the replica copies. For more information, see <u>Replicating metadata changes with replica modification sync.</u>	December 1, 2020
<u>Amazon S3 Bucket Keys</u>	Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (SSE-KMS). This new bucket-level key for server-side encryption can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see <u>Reducing the cost of SSE-KMS by using S3 Bucket Keys.</u>	December 1, 2020

<u>Amazon S3 Storage Lens</u>	S3 Storage Lens aggregate your metrics and displays the information in the Account snapshot section on the Amazon S3 console Buckets page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. For more information, see <u>Assessing your storage activity and usage with S3 Storage Lens</u> .	November 18, 2020
<u>Tracing S3 requests using AWS X-Ray</u>	Amazon S3 integrates with X-Ray to propagate the <u>trace context</u> and give you one request chain with <u>upstream and downstream</u> nodes. For more information, see <u>Tracing requests using X-Ray</u> .	November 16, 2020

<u>S3 Replication metrics</u>	S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. For more information, see <u>Replication metrics and Amazon S3 event notifications</u> .	November 9, 2020
<u>S3 Intelligent-Tiering Archive Access and Deep Archive Access</u>	S3 Intelligent-Tiering Archive Access and Deep Archive Access are additional storage tiers under S3 Intelligent-Tiering. For more information, see <u>Storage class for automatically optimizing frequently and infrequently accessed objects</u> .	November 9, 2020
<u>Delete marker replication</u>	With delete marker replication, you can ensure that delete markers are copied to your destination buckets for your replication rules. For more information, see <u>Using delete marker replication</u> .	November 9, 2020
<u>S3 Object Ownership</u>	Object Ownership is an S3 bucket setting that you can use to control ownership of new objects that are uploaded to your buckets. For more information, see <u>Using S3 Object Ownership</u> .	October 2, 2020

[Amazon S3 on Outposts](#)

With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and easily store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API. For more information, see [Using Amazon S3 on Outposts](#).

September 30, 2020

[Bucket owner condition](#)

You can use the Amazon S3 bucket owner condition to ensure that the buckets you use in your S3 operations belong to the AWS accounts that you expect. For more information, see [Bucket owner condition](#).

September 11, 2020

[S3 Batch Operations support for Object Lock Retention](#)

You can now use Batch Operations with S3 Object Lock to apply retention settings to many Amazon S3 objects at once. For more information, see [Setting S3 Object Lock Retention dates with S3 Batch Operations](#).

May 4, 2020

<u>S3 Batch Operations support for Object Lock Legal Hold</u>	You can now use Batch Operations with S3 Object Lock to add a legal hold to many Amazon S3 objects at once. For more information, see <u>Using S3 Batch Operations for setting S3 Object Lock Legal Hold.</u>	May 4, 2020
<u>Job tags for S3 Batch Operations</u>	You can add tags to your S3 Batch Operations jobs to control and label those jobs. For more information, see <u>Tags for S3 Batch Operations jobs.</u>	March 16, 2020
<u>Amazon S3 access points</u>	Amazon S3 access points simplify managing data access at scale for shared datasets in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations. For more information, see <u>Managing data access with Amazon S3 access points.</u>	December 2, 2019

<u>Access Analyzer for Amazon S3</u>	Access Analyzer for Amazon S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including accounts outside of your organization. For more information, see <u>Using Access Analyzer for Amazon S3</u> .	December 2, 2019
<u>S3 Replication Time Control (S3 RTC)</u>	S3 Replication Time Control (S3 RTC) replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes. For more information, see <u>Replicating objects using S3 Replication Time Control (S3 RTC)</u> .	November 20, 2019
<u>Same-Region Replication</u>	You can use Same-Region Replication (SRR) to copy objects across Amazon S3 buckets in the same AWS Region. For information about both Cross-Region Replication (CRR) and Same-Region Replication, see <u>Replication</u> .	September 18, 2019
<u>Cross-Region Replication support for S3 Object Lock</u>	Cross-Region Replication now supports Object Lock. For more information, see <u>What does Amazon S3 Replicate?</u> .	May 28, 2019

[S3 Batch Operations](#)

By using S3 Batch Operations, you can perform large-scale Batch Operations on Amazon S3 objects. S3 Batch Operations can run a single operation on lists of objects that you specify. A single job can perform the specified operation on billions of objects containing exabytes of data. For more information, see [Performing S3 Batch Operations](#).

April 30, 2019

[Asia Pacific \(Hong Kong\) Region](#)

Amazon S3 is now available in the Asia Pacific (Hong Kong) Region. For more information about Amazon S3 Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

April 24, 2019

[Added a new field to the server access logs](#)

Amazon S3 added the following new field to the server access logs: Transport Layer Security (TLS) version. For more information, see [Server access log format](#).

March 28, 2019

[New archive storage class](#)

Amazon S3 now offers a new archive storage class, S3 Glacier Deep Archive (DEEP_ARCHIVE), for storing rarely accessed objects. For more information, see [Storage Classes](#).

March 27, 2019

<u>Added new fields to the server access logs</u>	Amazon S3 added the following new fields to the server access logs: Host Id, Signature Version, Cipher Suite, Authentication Type, and Host Header. For more information, see <u>Server access log format</u> .	March 5, 2019
<u>Support for Parquet-formatted Amazon S3 Inventory files</u>	Amazon S3 now supports the <u>Apache Parquet (Parquet)</u> format in addition to the <u>Apache optimized row columnar (ORC)</u> and comma-separated values (CSV) file formats for inventory output files. For more information, see <u>Inventory</u> .	December 4, 2018
<u>S3 Object Lock</u>	Amazon S3 now offers Object Lock functionality that provides Write Once Read Many (WORM) protections for Amazon S3 objects. For more information, see <u>Locking Objects</u> .	November 26, 2018
<u>Restore speed upgrade</u>	Using Amazon S3 restore speed upgrade, you can change the speed of a restoration from the S3 Glacier Flexible Retrieval storage class to a faster speed while the restoration is in progress. For more information, see <u>Restoring Archived Objects</u> .	November 26, 2018

Restore Event Notifications

Amazon S3 Event Notifications now support initiation and completion events when restoring objects from the S3 Glacier Flexible Retrieval storage class. For more information, see [Event Notifications](#).

November 26, 2018

[PUT directly to the S3 Glacier Flexible Retrieval storage class](#)

The Amazon S3 PUT operation now supports specifying S3 Glacier Flexible Retrieval as the storage class when creating objects. Previously, you had to transition objects to the S3 Glacier Flexible Retrieval storage class from another Amazon S3 storage class. Also, when using S3 Cross-Region Replication (CRR), you can now specify S3 Glacier Flexible Retrieval as the storage class for replicated objects. For more information about the S3 Glacier Flexible Retrieval storage class, see [Storage Classes](#). For more information about specifying the storage class for replicated objects, [Replication Configuration Overview](#). For more information about the direct PUT to S3 Glacier Flexible Retrieval REST API changes, see [Document History: PUT directly to S3 Glacier Flexible Retrieval](#).

November 26, 2018

<u>New storage class</u>	Amazon S3 now offers a new storage class named S3 Intelligent-Tiering (INTELLIGENT_TIERING) that is designed for long-lived data with changing or unknown access patterns. For more information, see <u>Storage Classes</u> .	November 26, 2018
<u>Amazon S3 Block Public Access</u>	Amazon S3 now includes the ability to block public access to buckets and objects on a per-bucket or account-wide basis. For more information, see <u>Using Amazon S3 Block Public Access</u> .	November 15, 2018
<u>Filtering enhancements in Cross-Region Replication (CRR) rules</u>	In a CRR rule configuration, you can specify an object filter to choose a subset of objects to apply the rule to. Previously, you could filter only on an object key prefix. In this release, you can filter on an object key prefix, one or more object tags, or both. For more information, see <u>CRR Setup: Replication Configuration Overview</u> .	September 19, 2018

<u>New Amazon S3 Select features</u>	Amazon S3 Select now supports Apache Parquet input, queries on nested JSON objects, and two new Amazon CloudWatch monitoring metrics (<code>SelectScannedBytes</code> and <code>SelectReturnedBytes</code>).	September 5, 2018
<u>Updates now available over RSS</u>	You can now subscribe to an RSS feed to receive notifications about updates to the <i>Amazon S3 User Guide</i> .	June 19, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon S3 User Guide* before June 19, 2018.

Change	Description	Date
Code examples update	<p>Code examples updated:</p> <ul style="list-style-type: none">• C#—Updated all of the examples to use the task-based asynchronous pattern. For more information, see Amazon Web Services Asynchronous APIs for .NET in the <i>AWS SDK for .NET Developer Guide</i>. Code examples are now compliant with version 3 of the AWS SDK for .NET.• Java—Updated all of the examples to use the client builder model. For more information about the client builder model, see Creating Service Clients.•	April 30, 2018

Change	Description	Date
	<p>PHP—Updated all of the examples to use the AWS SDK for PHP 3.0. For more information about the AWS SDK for PHP 3.0, see AWS SDK for PHP.</p> <ul style="list-style-type: none">Ruby—Updated example code so that the examples work with the AWS SDK for Ruby version 3.	
Amazon S3 now reports S3 Glacier Flexible Retrieval and ONEZONE_IA storage classes to Amazon CloudWatch Logs storage metrics	<p>In addition to reporting actual bytes, these storage metrics include per-object overhead bytes for applicable storage classes (ONEZONE_IA, STANDARD_IA, and S3 Glacier Flexible Retrieval):</p> <ul style="list-style-type: none">For ONEZONE_IA and STANDARD_IA storage class objects, Amazon S3 reports objects smaller than 128 KB as 128 KB. For more information, see Understanding and managing Amazon S3 storage classes.For S3 Glacier Flexible Retrieval storage class objects, the storage metrics report the following overheads:<ul style="list-style-type: none">A 32 KB per-object overhead, charged at S3 Glacier Flexible Retrieval storage class pricingAn 8 KB per-object overhead, charged at STANDARD storage class pricing <p>For more information, see Transitioning objects using Amazon S3 Lifecycle.</p> <p>For more information about storage metrics, see Monitoring metrics with Amazon CloudWatch.</p>	April 30, 2018

Change	Description	Date
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.</p>	April 4, 2018
Amazon S3 Select	<p>Amazon S3 now supports retrieving object content based on an SQL expression. For more information, see Querying data in place with Amazon S3 Select.</p>	April 4, 2018
Asia Pacific (Osaka-Local) Region	<p>Amazon S3 is now available in the Asia Pacific (Osaka-Local) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the AWS General Reference.</p>	February 12, 2018
	⚠ Important <p>You can use the Asia Pacific (Osaka-Local) Region only in conjunction with the Asia Pacific (Tokyo) Region. To request access to Asia Pacific (Osaka-Local) Region, contact your sales representative.</p>	
Amazon S3 Inventory creation timestamp	<p>Amazon S3 Inventory now includes a timestamp of the date and start time of the creation of the Amazon S3 Inventory report. You can use the timestamp to determine changes in your Amazon S3 storage from the start time of when the inventory report was generated.</p>	January 16, 2018
Europe (Paris) Region	<p>Amazon S3 is now available in the Europe (Paris) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the AWS General Reference.</p>	December 18, 2017

Change	Description	Date
China (Ningxia) Region	Amazon S3 is now available in the China (Ningxia) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	November 29, 2017
Support for ORC-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache optimized row columnar (ORC) format in addition to comma-separated values (CSV) file format for inventory output files. Also, you can now query Amazon S3 inventory using standard SQL by using Amazon Athena, Amazon Redshift Spectrum, and other tools such as Presto , Apache Hive , and Apache Spark . For more information, see Cataloging and analyzing your data with S3 Inventory .	November 17, 2017
Default encryption for S3 buckets	Amazon S3 default encryption provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The objects are encrypted using server-side encryption with either Amazon S3 managed keys (SSE-S3) or AWS managed keys (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets .	November 06, 2017
Encryption status in Amazon S3 Inventory	Amazon S3 now supports including encryption status in Amazon S3 Inventory so you can see how your objects are encrypted at rest for compliance auditing or other purposes. You can also configure to encrypt Amazon S3 Inventory with server-side encryption (SSE) or SSE-KMS so that all inventory files are encrypted accordingly. For more information, see Cataloging and analyzing your data with S3 Inventory .	November 06, 2017

Change	Description	Date
Cross-Region Replication (CRR) enhancements	<p>Cross-Region Replication now supports the following:</p> <ul style="list-style-type: none">• In a cross-account scenario, you can add a CRR configuration to change replica ownership to the AWS account that owns the destination bucket. For more information, see Changing the replica owner.• By default, Amazon S3 does not replicate objects in your source bucket that are created using server-side encryption using keys stored in AWS KMS. In your CRR configuration, you can now direct Amazon S3 to replicate these objects. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).	November 06, 2017
Europe (London) Region	Amazon S3 is now available in the Europe (London) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 13, 2016
Canada (Central) Region	Amazon S3 is now available in the Canada (Central) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	December 8, 2016

Change	Description	Date
Object tagging	<p>Amazon S3 now supports object tagging. Object tagging enables you to categorize storage. Object key name prefixes also enable you to categorize storage, object tagging adds another dimension to it.</p> <p>There are added benefits tagging offers. These include:</p> <ul style="list-style-type: none"> • Object tags enable fine-grained access control of permissions (for example, you could grant an IAM user permissions to read-only objects with specific tags). • Fine-grained control in specifying lifecycle configuration. You can specify tags to select a subset of objects to which lifecycle rule applies. • If you have Cross-Region Replication (CRR) configured, Amazon S3 can replicate the tags. You must grant necessary permission to the IAM role created for Amazon S3 to assume to replicate objects on your behalf. • You can also customize CloudWatch metrics and CloudTrail events to display information by specific tag filters. <p>For more information, see Categorizing your storage using tags.</p>	November 29, 2016
Amazon S3 Lifecycle now supports tag-based filters	Amazon S3 now supports tag-based filtering in lifecycle configuration. You can now specify lifecycle rules in which you can specify a key prefix, one or more object tags, or a combination of both to select a subset of objects to which the lifecycle rule applies. For more information, see Managing the lifecycle of objects .	November 29, 2016

Change	Description	Date
CloudWatch request metrics for buckets	<p>Amazon S3 now supports CloudWatch metrics for requests made on buckets. When you enable these metrics for a bucket, the metrics report at 1-minute intervals. You can also configure which objects in a bucket will report these request metrics. For more information, see Monitoring metrics with Amazon CloudWatch.</p>	November 29, 2016
Amazon S3 Inventory	<p>Amazon S3 now supports storage inventory. Amazon S3 Inventory provides a flat-file output of your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or a shared prefix (that is, objects that have names that begin with a common string).</p> <p>For more information, see Cataloging and analyzing your data with S3 Inventory.</p>	November 29, 2016
Amazon S3 Analytics – Storage Class Analysis	<p>The new Amazon S3 analytics – storage class analysis feature observes data access patterns to help you determine when to transition less frequently accessed STANDARD storage to the STANDARD_IA (IA, for infrequent access) storage class. After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. This feature also includes a detailed daily analysis of your storage usage at the specified bucket, prefix, or tag level that you can export to an S3 bucket.</p>	November 29, 2016
New Expedited and Bulk data retrievals when restoring archived objects from S3 Glacier	<p>Amazon S3 now supports Expedited and Bulk data retrievals in addition to Standard retrievals when restoring objects archived to S3 Glacier. For more information, see Restoring an archived object.</p>	November 21, 2016

Change	Description	Date
CloudTrail object logging	CloudTrail supports logging Amazon S3 object level API operations such as <code>GetObject</code> , <code>PutObject</code> , and <code>DeleteObject</code> . You can configure your event selectors to log object level API operations. For more information, see Logging Amazon S3 API calls using AWS CloudTrail .	November 21, 2016
US East (Ohio) Region	Amazon S3 is now available in the US East (Ohio) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	October 17, 2016
IPv6 support for Amazon S3 Transfer Acceleration	Amazon S3 now supports Internet Protocol version 6 (IPv6) for Amazon S3 Transfer Acceleration. You can connect to Amazon S3 over IPv6 by using the new dual-stack for Transfer Acceleration endpoint. For more information, see Getting started with Amazon S3 Transfer Acceleration .	October 6, 2016
IPv6 support	Amazon S3 now supports Internet Protocol version 6 (IPv6). You can access Amazon S3 over IPv6 by using dual-stack endpoints. For more information, see Making requests to Amazon S3 over IPv6 in the <i>Amazon S3 API Reference</i> .	August 11, 2016
Asia Pacific (Mumbai) Region	Amazon S3 is now available in the Asia Pacific (Mumbai) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i> .	June 27, 2016

Change	Description	Date
Amazon S3 Transfer Acceleration	<p>Amazon S3 Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of Amazon CloudFront globally distributed edge locations.</p> <p>For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.</p>	April 19, 2016
Lifecycle support to remove expired object delete markers	Lifecycle configuration Expiration action now allows you to direct Amazon S3 to remove expired object delete markers in a/ versioned bucket. For more information, see Elements to describe lifecycle actions .	March 16, 2016

Change	Description	Date
Bucket lifecycle configuration now supports action to stop incomplete multipart uploads	<p>Bucket lifecycle configuration now supports the <code>AbortIncompleteMultipartUpload</code> action that you can use to direct Amazon S3 to stop multipart uploads that don't complete within a specified number of days after being initiated. When a multipart upload becomes eligible for a stop operation, Amazon S3 deletes any uploaded parts and stops the multipart upload.</p> <p>For conceptual information, see the following topics in the <i>Amazon S3 User Guide</i>:</p> <ul style="list-style-type: none">• Aborting a multipart upload• Elements to describe lifecycle actions <p>The following API operations have been updated to support the new action:</p> <ul style="list-style-type: none">• PUT Bucket lifecycle – The XML configuration now allows you to specify the <code>AbortIncompleteMultipartUpload</code> action in a lifecycle configuration rule.• List Parts and Initiate Multipart Upload – Both of these API operations now return two additional response headers (<code>x-amz-abort-date</code>, and <code>x-amz-abort-rule-id</code>) if the bucket has a lifecycle rule that specifies the <code>AbortIncompleteMultipartUpload</code> action. These headers in the response indicate when the initiated multipart upload becomes eligible for a stop operation and which lifecycle rule is applicable.	March 16, 2016

Change	Description	Date
Asia Pacific (Seoul) Region	<p>Amazon S3 is now available in the Asia Pacific (Seoul) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the <i>AWS General Reference</i>.</p>	January 6, 2016
New condition key and a multipart upload change	<p>IAM policies now support an Amazon S3 <code>s3:x-amz-storage-class</code> condition key. For more information, see Bucket policy examples using condition keys.</p> <p>You no longer need to be the initiator of a multipart upload to upload parts and complete the upload. For more information, see Multipart upload API and permissions.</p>	December 14, 2015
Renamed the US Standard Region	<p>Changed the Region name string from "US Standard" to "US East (N. Virginia)." This is only a Region name update, there is no change in the functionality.</p>	December 11, 2015
New storage class	<p>Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.</p> <p>Lifecycle configuration feature updates now allow you to transition objects to the STANDARD_IA storage class. For more information, see Managing the lifecycle of objects.</p> <p>Previously, the Cross-Region Replication feature used the storage class of the source object for object replicas. Now, when you configure Cross-Region Replication, you can specify a storage class for the object replica created in the destination bucket. For more information, see Replicating objects within and across Regions.</p>	September 16, 2015

Change	Description	Date
AWS CloudTrail integration	New AWS CloudTrail integration allows you to record Amazon S3 API activity in your S3 bucket. You can use CloudTrail to track S3 bucket creations or deletions, access control modifications, or lifecycle configuration changes. For more information, see Logging Amazon S3 API calls using AWS CloudTrail .	September 1, 2015
Bucket limit increase	Amazon S3 now supports bucket limit increases. By default, customers can create up to 100 buckets in their AWS account. Customers who need additional buckets can increase that limit by submitting a service limit increase. For information about how to increase your bucket limit, go to AWS service quotas in the AWS <i>General Reference</i> . For more information, see Using the AWS SDKs and Bucket quotas, limitations, and restrictions .	August 4, 2015
Consistency model update	Amazon S3 now supports read-after-write consistency for new objects added to Amazon S3 in the US East (N. Virginia) Region. Prior to this update, all Regions except US East (N. Virginia) Region supported read-after-write consistency for new objects uploaded to Amazon S3. With this enhancement, Amazon S3 now supports read-after-write consistency in all Regions for new objects added to Amazon S3. Read-after-write consistency allows you to retrieve objects immediately after creation in Amazon S3. For more information, see Regions .	August 4, 2015
Event notifications	Amazon S3 Event Notifications have been updated to add notifications when objects are deleted and to add filtering on object names with prefix and suffix matching. For more information, see Amazon S3 Event Notifications .	July 28, 2015

Change	Description	Date
Amazon CloudWatch integration	<p>New Amazon CloudWatch integration allows you to monitor and set alarms on your Amazon S3 usage through CloudWatch metrics for Amazon S3. Supported metrics include total bytes for Standard storage, total bytes for Reduced-Redundancy Storage, and total number of objects for a given S3 bucket. For more information, see Monitoring metrics with Amazon CloudWatch.</p>	July 28, 2015
Support for deleting and emptying non-empty buckets	<p>Amazon S3 now supports deleting and emptying non-empty buckets. For more information, see Emptying a bucket.</p>	July 16, 2015
Bucket policies for Amazon VPC endpoints	<p>Amazon S3 has added support for bucket policies for virtual private cloud (VPC) (VPC) endpoints. You can use S3 bucket policies to control access to buckets from specific VPC endpoints, or specific VPCs. VPC endpoints are easy to configure, are highly reliable, and provide a secure connection to Amazon S3 without requiring a gateway or a NAT instance. For more information, see Controlling access from VPC endpoints with bucket policies.</p>	April 29, 2015
Event notifications	<p>Amazon S3 Event Notifications have been updated to support the switch to resource-based permissions for AWS Lambda functions. For more information, see Amazon S3 Event Notifications.</p>	April 9, 2015
Cross-Region Replication	<p>Amazon S3 now supports Cross-Region Replication. Cross-Region Replication is the automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects within and across Regions.</p>	March 24, 2015

Change	Description	Date
Event notifications	<p>Amazon S3 now supports new event types and destinations in a bucket notification configuration. Prior to this release, Amazon S3 supported only the <code>s3:ReducedRedundancyLostObject</code> event type and an Amazon SNS topic as the destination. For more information about the new event types, see Amazon S3 Event Notifications.</p>	November 13, 2014
Server-side encryption with customer-provided encryption keys	<p>Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS)</p> <p>Amazon S3 now supports server-side encryption using AWS KMS. This feature allows you to manage the envelope key through AWS KMS, and Amazon S3 calls AWS KMS to access the envelope key within the permissions you set.</p> <p>For more information about server-side encryption with AWS KMS, see Protecting Data Using Server-Side Encryption with AWS Key Management Service.</p>	November 12, 2014
Europe (Frankfurt) Region	Amazon S3 is now available in the Europe (Frankfurt) Region.	October 23, 2014
Server-side encryption with customer-provided encryption keys	<p>Amazon S3 now supports server-side encryption using customer-provided encryption keys (SSE-C). Server-side encryption enables you to request Amazon S3 to encrypt your data at rest. When using SSE-C, Amazon S3 encrypts your objects with the custom encryption keys that you provide. Since Amazon S3 performs the encryption for you, you get the benefits of using your own encryption keys without the cost of writing or executing your own encryption code.</p> <p>For more information about SSE-C, see Server-Side Encryption (Using Customer-Provided Encryption Keys).</p>	June 12, 2014

Change	Description	Date
Lifecycle support for versioning	Prior to this release, lifecycle configuration was supported only on nonversioned buckets. Now you can configure lifecycle on both nonversioned and versioning-enabled buckets. For more information, see Managing the lifecycle of objects .	May 20, 2014
Access control topics revised	Revised Amazon S3 access control documentation. For more information, see Identity and Access Management for Amazon S3 .	April 15, 2014
Server access logging topic revised	Revised server access logging documentation. For more information, see Logging requests with server access logging .	November 26, 2013
.NET SDK samples updated to version 2.0	.NET SDK samples in this guide are now compliant to version 2.0.	November 26, 2013
SOAP Support Over HTTP deprecated	SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features will not be supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.	September 20, 2013
IAM policy variable support	<p>IAM policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, see IAM Policy Variables Overview in the <i>IAM User Guide</i>.</p> <p>For examples of policy variables in Amazon S3, see Identity-based policy examples for Amazon S3.</p>	April 3, 2013

Change	Description	Date
Console support for Requester Pays	You can now configure your bucket for Requester Pays by using the Amazon S3 console. For more information, see Using Requester Pays buckets for storage transfers and usage.	December 31, 2012
Root domain support for website hosting	Amazon S3 now supports hosting static websites at the root domain. Visitors to your website can access your site from their browser without specifying www in the web address (for example, they can use example.com instead of www.example.com). Many customers already host static websites on Amazon S3 that are accessible from a www subdomain (for example, www.example.com). Previously, to support root domain access, you needed to run your own web server to proxy root domain requests from browsers to your website on Amazon S3. Running a web server to proxy requests introduces additional costs, operational burden, and another potential point of failure. Now, you can take advantage of the high availability and durability of Amazon S3 for both www and root domain addresses. For more information, see Hosting a static website using Amazon S3 .	December 27, 2012
Console revision	Amazon S3 console has been updated. The documentation topics that refer to the console have been revised accordingly.	December 14, 2012

Change	Description	Date
Support for Archiving Data to S3 Glacier	<p>Amazon S3 now supports a storage option that enables you to utilize S3 Glacier's low-cost storage service for data archival. To archive objects, you define archival rules identifying objects and a time frame when you want Amazon S3 to archive these objects to S3 Glacier. You can easily set the rules on a bucket using the Amazon S3 console or programmatically using the Amazon S3 API or AWS SDKs.</p> <p>For more information, see Managing the lifecycle of objects.</p>	November 13, 2012
Support for Website Page Redirects	<p>For a bucket that is configured as a website, Amazon S3 now supports redirecting a request for an object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect.</p> <p>For information about hosting websites, see Hosting a static website using Amazon S3.</p>	October 4, 2012
Support for Cross-Origin Resource Sharing (CORS)	<p>Amazon S3 now supports Cross-Origin Resource Sharing (CORS). CORS defines a way in which client web applications that are loaded in one domain can interact with or access resources in a different domain. With CORS support in Amazon S3, you can build rich client-side web applications on top of Amazon S3 and selectively allow cross-domain access to your Amazon S3 resources. For more information, see Using cross-origin resource sharing (CORS).</p>	August 31, 2012
Support for Cost Allocation Tags	<p>Amazon S3 now supports cost allocation tagging, which allows you to label S3 buckets so you can more easily track their cost against projects or other criteria. For more information about using tagging for buckets, see Using cost allocation S3 bucket tags.</p>	August 21, 2012

Change	Description	Date
Support for MFA-protected API access in bucket policies	<p>Amazon S3 now supports MFA-protected API access, a feature that can enforce AWS Multi-Factor Authentication for an extra level of security when accessing your Amazon S3 resources. It is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, go to AWS Multi-Factor Authentication. You can now require MFA authentication for any requests to access your Amazon S3 resources.</p> <p>To enforce MFA authentication, Amazon S3 now supports the <code>aws:MultiFactorAuthAge</code> key in a bucket policy. For an example bucket policy, see Requiring MFA.</p>	July 10, 2012
Object Expiration support	You can use Object Expiration to schedule automatic removal of data after a configured time period. You set object expiration by adding lifecycle configuration to a bucket.	27 December 2011
New Region supported	Amazon S3 now supports the South America (São Paulo) Region. For more information, see Accessing an Amazon S3 bucket .	December 14, 2011
Multi-Object Delete	Amazon S3 now supports Multi-Object Delete API that enables you to delete multiple objects in a single request. With this feature, you can remove large numbers of objects from Amazon S3 more quickly than using multiple individual DELETE requests. For more information, see Deleting Amazon S3 objects .	December 7, 2011
New Region supported	Amazon S3 now supports the US West (Oregon) Region. For more information, see Buckets and Regions .	November 8, 2011
Documentation Update	Documentation bug fixes.	November 8, 2011

Change	Description	Date
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none"> • New server-side encryption sections using the AWS SDK for PHP and the AWS SDK for Ruby (see Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)). 	October 17, 2011
Server-side encryption support	<p>Amazon S3 now supports server-side encryption. It enables you to request Amazon S3 to encrypt your data at rest, that is, encrypt your object data when Amazon S3 writes your data to disks in its data centers. In addition to REST API updates, the AWS SDK for Java and .NET provide necessary functionality to request server-side encryption. You can also request server-side encryption when uploading objects using the AWS Management Console. To learn more about data encryption, go to Using Data Encryption.</p>	October 4, 2011
Documentation Update	<p>In addition to documentation bug fixes, this release includes the following enhancements:</p> <ul style="list-style-type: none"> • Added Ruby and PHP samples to the Making requests in the <i>Amazon S3 API Reference</i> section. • Added sections describing how to generate and use presigned URLs. For more information, see Sharing objects with presigned URLs and Sharing objects with presigned URLs. • Updated an existing section to introduce AWS Explorers for Eclipse and Visual Studio. For more information, see Developing with Amazon S3 using the AWS SDKs in the <i>Amazon S3 API Reference</i>. 	September 22, 2011

Change	Description	Date
Support for sending requests using temporary security credentials	<p>In addition to using your AWS account and IAM user security credentials to send authenticated requests to Amazon S3, you can now send requests using temporary security credentials you obtain from AWS Identity and Access Management (IAM). You can use the AWS Security Token Service API or the AWS SDK wrapper libraries to request these temporary credentials from IAM. You can request these temporary security credentials for your own use or hand them out to federated users and applications. This feature enables you to manage your users outside AWS and provide them with temporary security credentials to access your AWS resources.</p> <p>For more information, see Making requests in the <i>Amazon S3 API Reference</i>.</p> <p>For more information about IAM support for temporary security credentials, see Temporary Security Credentials in the <i>IAM User Guide</i>.</p>	August 3, 2011
Multipart Upload API extended to enable copying objects up to 5 TB	<p>Prior to this release, Amazon S3 API supported copying objects of up to 5 GB in size. To enable copying objects larger than 5 GB, Amazon S3 now extends the multipart upload API with a new operation, <code>Upload Part (Copy)</code>. You can use this multipart upload operation to copy objects up to 5 TB in size. For more information, see Copying, moving, and renaming objects.</p> <p>For conceptual information about multipart upload API, see Uploading and copying objects using multipart upload in Amazon S3.</p>	June 21, 2011
SOAP API calls over HTTP disabled	To increase security, SOAP API calls over HTTP are disabled. Authenticated and anonymous SOAP requests must be sent to Amazon S3 using SSL.	June 6, 2011

Change	Description	Date
IAM enables cross-account delegation	<p>Previously, to access an Amazon S3 resource, an IAM user needed permissions from both the parent AWS account and the Amazon S3 resource owner. With cross-account access, the IAM user now only needs permission from the owner account. That is, If a resource owner grants access to an AWS account, the AWS account can now grant its IAM users access to these resources.</p> <p>For more information, see Creating a role to delegate permissions to an IAM user in the <i>IAM User Guide</i>.</p> <p>For more information on specifying principals in a bucket policy, see Principals for bucket policies.</p>	June 6, 2011
New link	This service's endpoint information is now located in the <i>AWS General Reference</i> . For more information, go to Regions and Endpoints in the AWS General Reference .	March 1, 2011
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3 .	June 6, 2011

Change	Description	Date
<p>This service's endpoint information is now located in the <i>AWS General Reference</i>. For more information, go to Regions and Endpoints in the AWS General Reference.</p>	March 1, 2011	
Support for hosting static websites in Amazon S3	<p>Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, <code>http://mywebsite.com/subfolder</code>) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.</p>	February 17, 2011
Response Header API Support	<p>The GET Object REST API now allows you to change the response headers of the REST GET Object request for each request. That is, you can alter object metadata in the response, without altering the object itself. For more information, see Downloading objects.</p>	January 14, 2011
Large object support	<p>Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 GB to 5 TB. If you are using the REST API, you can upload objects of up to 5 GB in a single PUT operation. For larger objects, you must use the Multipart Upload REST API to upload objects in parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.</p>	December 9, 2010

Change	Description	Date
Multipart upload	Multipart upload enables faster, more flexible uploads into Amazon S3. It allows you to upload a single object as a set of parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3 .	November 10, 2010
Canonical ID support in bucket policies	You can now specify canonical IDs in bucket policies. For more information, see Principals for bucket policies	September 17, 2010
Amazon S3 works with IAM	This service now integrates with AWS Identity and Access Management (IAM). For more information, go to AWS services that work with IAM in the <i>IAM User Guide</i> .	September 2, 2010
Notifications	The Amazon S3 notifications feature enables you to configure a bucket so that Amazon S3 publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic when Amazon S3 detects a key event on a bucket. For more information, see Setting Up Notification of Bucket Events .	July 14, 2010
Bucket policies	Bucket policies are an access management system that you use to set access permissions across buckets, objects, and sets of objects. This functionality supplements and in many cases replaces access control lists. For more information, see Bucket policies for Amazon S3 .	July 6, 2010
Path-style syntax available in all Regions	Amazon S3 now supports the path-style syntax for any bucket in the US Classic Region, or if the bucket is in the same Region as the endpoint of the request. For more information, see Virtual Hosting .	June 9, 2010
New endpoint for Europe (Ireland)	Amazon S3 now provides an endpoint for Europe (Ireland) : <code>http://s3-eu-west-1.amazonaws.com</code> .	June 9, 2010

Change	Description	Date
Console	You can now use Amazon S3 through the AWS Management Console. You can read about all of the Amazon S3 functionality in the console in the Amazon Simple Storage Service User Guide.	June 9, 2010
Reduced Redundancy	Amazon S3 now enables you to reduce your storage costs by storing objects in Amazon S3 with reduced redundancy. For more information, see Reduced Redundancy Storage .	May 12, 2010
New Region supported	Amazon S3 now supports the Asia Pacific (Singapore) Region. For more information, see Buckets and Regions .	April 28, 2010
Object Versioning	This release introduces object versioning. All objects now can have a key and a version. If you enable versioning for a bucket, Amazon S3 gives all objects added to a bucket a unique version ID. This feature enables you to recover from unintended overwrites and deletions. For more information, see Versioning and Using Versioning .	February 8, 2010
New Region supported	Amazon S3 now supports the US West (N. California) Region. The new endpoint for requests to this Region is <code>s3-us-west-1.amazonaws.com</code> . For more information, see Buckets and Regions .	December 2, 2009
AWS SDK for .NET	AWS now provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using .NET language-specific API operations instead of REST or SOAP. These libraries provide basic functions (not included in the REST or SOAP APIs), such as request authentication, request retries, and error handling so that it's easier to get started. For more information about language-specific libraries and resources, see Developing with Amazon S3 using the AWS SDKs in the Amazon S3 API Reference .	November 11, 2009
